

Economic and Psychological Returns to Social Relationships: Alleviating Constraints to Network Formation in Malawi*

Gabriella Fleischman[†]

Abstract

What are the causal effects of new social relationships, and do returns to link formation vary within versus across social class? I conduct a field experiment among women in rural Malawi who relocate to their husband's home village, thereby disrupting their preexisting social ties. I randomly assign low socioeconomic status (SES) with the opportunity to send meal invitations to neighboring women willing to receive them. I experimentally vary whether the names appearing on the list are all low-SES, all high-SES, or both. I cross-randomize the invitation-sending arms with an in-kind meal subsidy, which weakens financial constraints to meal-sharing. Eighty-one percent of women send invitations across all treatment arms, while the meal subsidy increases invitations to high-SES women only among participants who can send invitations to both. I show that there are substantial but differential returns to cross- and same-SES linkages: one year later, participants with the opportunity to invite higher-SES guests are 20% more likely to earn income from self-employment and report a 0.21 SD improvement in food security, while women with the opportunity to invite guests within-SES experience a 0.23 SD (30%) reduction in depressive symptoms. This highlights a trade-off in network formation, where social ties that offer economic advancement may come at the expense of relationships that improve psychological well-being.

*I am deeply grateful to Marcella Alsan, Emily Breza, Reshmaan Hussam, and Eliana La Ferrara for their guidance and support. I am indebted to James Mkandawire, Davie Chitenje, Tombozgani Mhango, the Invest in Knowledge Initiative (IKI) data collection team, and Stella Idadi, without whom this work would not have been possible. I am thankful for useful comments and suggestions from Alice Danon, Laura Derksen, Akib Khan, Lauren Rice, Daniel Suryadarma, Christina Qiu, Sarah Vincent, and participants at numerous seminars and conferences. Reagan Curtis and Samira Mathur provided excellent research assistance. I gratefully acknowledge financial support from the Weiss Fund, the Adrienne Hall Fund at the Harvard Kennedy School Women and Public Policy Program, the Institute for Quantitative Social Sciences at Harvard University, the Center for International Development at the Harvard Kennedy School, the Graduate School of Arts and Sciences at Harvard University, the Center for African Studies at Harvard University, and SurveyCTO. This study received IRB approval from Harvard University protocol number IRB22-0484 and the Malawi National Committee on Research in Social Sciences and Humanities protocol P.05/23/760. The experiment was pre-registered under RCT ID AEARCTR-0013644.

1 Introduction

Economic theory posits that social connections are both fundamental for market functions and intrinsically utility-generating (Becker, 1974; Bentham, 1789). Empirically, the economics literature has linked social interactions with employment, economic mobility, financial inclusion and increased savings (Banerjee et al., 2013; Beaman, 2012; Chetty et al., 2022a,b).¹ Social connections might be even more critical in low-income contexts, where informal risk-sharing provides services to fill missing markets (Coate and Ravallion, 1993; Fafchamps and Lund, 2003; Karlan et al., 2017; La Ferrara, 2003; Ligon and Schechter, 2003, 2012; Munshi, 2014; Townsend, 1994; Udry, 1994). At the same time, a wealth of descriptive evidence, largely in fields outside economics, finds that social relationships are a powerful predictor of well-being (Algren et al., 2020; Morrish et al., 2022; Rico-Uribe et al., 2018).

What are the causal effects of forming new relationships, and are there different returns to interacting with someone in the same social class or in a higher social class? Despite the view that social interactions matter for markets and well-being, endogenous link formation makes the causal effects of social connection difficult to study. There is even less economics research identifying what encourages or constrains social connections from arising, or characterizing trade-offs between social ties.² This study asks these questions among a sample of women who moved across rural villages in Malawi, usually for marriage. Having been uprooted from their families and existing social networks, these women are in a circumstance that creates the conditions for social isolation, loneliness, and economic vulnerability. Given that 73% of societies worldwide are traditionally patrilocal (women move to their husband’s villages), and there is evidence that patrilocality is becoming increasingly common, this reflects a common experience for rural women (Murdock, 1967; Shenk et al., 2019).

I conduct a randomized controlled trial that exogenously provides these women with opportunities to link with each other. I randomly assign 1,200 low socioeconomic status (SES) female migrants to receive a list of the names of neighboring women willing to

¹There is a rapidly growing base of empirical evidence on the role of social networks for economic outcomes, especially within development economics. A large body of work takes the social network as a fixed object through which information, technologies, or norms diffuse (Banerjee et al., 2013, 2019, 2024b; Beaman, 2012; Beaman and Magruder, 2012; Beaman et al., 2021; Breza and Chandrasekhar, 2019; Breza et al., 2024; Chandrasekhar et al., 2018, 2022; Conley and Udry, 2010; Duflo et al., 2023; Foster and Rosenzweig, 1995; Jensen, 2007; Iacobelli and Singh, 2020; Kondylis et al., 2023). A smaller literature evaluates shocks to network structure, such as introducing people through group-based or mentoring programs (Asiedu et al., 2025; Feigenberg et al., 2013; Schechter and Vasudevan, 2024; Vasilaky and Leonard, 2018; Vasilaky, 2013), or asks how interventions lead to social network changes (Banerjee et al., 2024a; Derksen and Souza, 2024).

²Classic works in sociology and political science addressing theoretical trade-offs across network links and structures include Blau (1977); Bourdieu and Passeron (1977); Coleman (1988); Granovetter (1973); Lin (2001); Portes (1998); Putnam (2000); Tilly (1998).

receive meal invitations and the opportunity to send them invitations. I experimentally vary whether the names appearing on the list are all other low-SES women, all high-SES women, or a random mix of both low-SES and high-SES women. I cross-randomize the invitation-sending arms with an in-kind meal subsidy, which weakens financial constraints to meal-sharing. To establish which women are willing to receive invitations, I first ask participants if they would like their name to be on a list from which others can send them an invitation for a shared meal, which 99% of women sign up for. I then show treated women (*Inviters*) six names of their neighbors from that list (*Guests*) and offer to send from zero to five invitations delivered through an enumerator. Although women in the experiment are acquainted with one another, the intervention serves as a genuine shock to status quo social interactions: 81% of Inviters send an invitation through the intervention, 99% of which are to women outside their self-reported baseline networks.

One year later, the pooled Inviter treatment leads to a 0.13 standard deviation (SD) increase in an index of food security and a 0.16 SD (21%) reduction in experiencing mild-to-severe depressive symptoms. The treatment effects on food security are significantly higher among Inviters who I randomize to only interact with high-SES women (*Inviters with the High-SES Guest List*) relative to Inviters who only interact with low-SES women (*Inviters with the Low-SES Guest List*) (a 0.21 SD treatment effect versus 0.07 SD, $p = 0.026$). Conversely, the treatment effects on depressive symptoms are significantly larger among Inviters with the Low-SES Guest List relative to Inviters with the High-SES Guest List (a 10.7 percentage point reduction versus a 4.5 percentage point reduction, $p = 0.035$). The economic effects are driven by Inviters with the High-SES Guest List earning income from new self-employment activities within just one month of the intervention, while there are no impacts on borrowing or food transfers. These results are especially impactful given the context: Malawi was in a severe food shortage during the study—the fifth that Malawi has experienced in the twenty-first century—where an estimated 28% of the population suffered acute food insecurity ([UNICEF, 2025](#)).

Given that extraordinary benefits appear to arise from little more than a nudge, what prevents these interactions from happening organically? I first ask if there are barriers that preclude individuals from interacting with specific types of people. The probability of sending an invitation or sharing a meal is not different across the groups of women who are constrained by the experiment to send an invitation only to low-SES or high-SES women, implying that women are *not* restricted to interact only with other people within their own social class, for example, through social norms. At the same time, I do find that interaction with low-SES and high-SES women yield meaningfully different outcomes.

Is social interaction restricted by financial costs? To answer this question, I cross-randomize a voucher that is redeemable at a local butcher. Meat is a well-liked yet expensive and rarely consumed good in this setting, so the voucher effectively reduces

the price of a nice meal to the same price as an everyday meal. The voucher does not change invitation-sending or meal-sharing in either of the groups with the Low-SES-only or High-SES-only Guest Lists. Even when a high-quality meal is unaffordable, sending invitations to either type is better than nothing. However, among Inviters who can invite any type of woman (*Inviters with the Random Guest List*), receipt of the voucher significantly increases the likelihood of inviting high-SES women, driven by women who also invite a low-SES woman. This implies that there is a set of low-SES women who prefer to only interact with other low-SES women when the price of meat is high. When they can afford to serve a nice meal, they also decide to initiate social ties across SES, but not at the expense of within-SES connections.

I interpret these findings through the lens of a conceptual model of social network formation under budget constraints, where relationships have both intrinsic and instrumental value. I make two key assumptions: first, that low- and high-SES relationships are each better at producing one type of benefit, and second, that the benefits of relationships are increasing in financial investments in social interaction. The first assumption implies that agents benefit from economic diversity in their networks, since low-SES relationships yield important intrinsic utility benefits that are not substitutable for high-SES links. In the model, the trade-off between initiating an economically diverse set of interactions with both high- and low-SES women, versus initiating a homophilic set of interactions with only other low-SES women, changes with the price of a nice meal. This generates a key insight: the high prices of the most valuable social activities act as a driver of homophily, implying that income-based homophily—which is defined by one group being unable to afford high-priced goods—is self-reinforcing.

This paper contributes to the literature on the economic value of social relationships. A large and classic literature in development economics evaluates the presence and efficiency of risk-smoothing—across people, time, plots, and places—within villages in low-income countries (Attanasio et al., 2012; Beaman et al., 2014; Ligon, 1998; Ligon et al., 2002; Kinnan and Townsend, 2012; Kinnan et al., 2024; Mobarak and Rosenzweig, 2013; Rozensweig and Stark, 1989; Santos and Barrett, 2011; Townsend, 1994). This literature is predicated on the idea that social ties are an important mechanism through which people share risk, but it is rare to find and evaluate exogenous network shocks, especially without technological innovation (Jack and Suri, 2014; Riley, 2018). This paper provides causal evidence that an exogenous network link has large impacts on consumption smoothing, implying that risk-smoothing is limited by frictions in creating new social relationships. Furthermore, the fact that these economic benefits come from high-SES ties speaks to a growing body of work describing the positive relationship between peers’ economic outcomes and one’s own economic outcomes (Bergman et al., 2024; Cannon et al., 2024; Chetty et al., 2016, 2022b; Laschever, 2013; Linde and Egede, 2023; Ludwig et al., 2013; Mallah, 2026;

Patel and Wolfe, 2024; Sacerdote, 2011). This paper significantly expands the external validity of this evidence base, as a paper that is experimental, in low-income country, and outside of an educational context.³

The second primary contribution of the paper is to identify a causal relationship between social relationships and mental health. I find that new relationships lead to large reductions in depressive symptoms one year after the initial interaction, which extends a large body of evidence documenting a powerful relationship between social connection and well-being. The evidence to date is descriptive (Algren et al., 2020; Morrish et al., 2022; Rico-Uribe et al., 2018), or experimentally evaluates the impacts of one-time social interactions with strangers (Epley and Schroeder, 2014; Epley et al., 2022). These results suggest that the social isolation accompanying low-income may be an important mechanism underlying the relationship between low-income and poor mental health and loneliness (Banerjee et al., 2023; Ridley et al., 2020; Surkalim et al., 2022), a pathway that has been understudied empirically relative to scarcity and stress mechanisms (Annan and Archibong, 2023; Haushofer and Salicath, 2023). Furthermore, I provide a practicable intervention that reduces long-term mild-to-severe depressive symptoms among low-income and marginalized women by 30%.⁴

Lastly, I contribute to the social networks literature. While a nascent body of evidence in economics shows that network externalities can causally limit social network formation (Anders and Pallais, 2025; Banerjee et al., 2024a), my experiment demonstrates how individual-level constraints to meaningful social interactions can inhibit social linking even when meeting opportunities are available and people want to link, with large economic consequences. Furthermore, my experiment presents causal evidence identifying a mechanism underlying homophily in choices over with whom to interact. Despite the widespread prevalence of homophily and its economic relevance, we have minimal causal evidence identifying *why* social networks become and remain homophilic (Jackson, 2025; McPherson et al., 2001; Verbrugge, 1977).⁵ I show that the financial cost of valuable social interaction inhibits lower-income women from initiating economically

³Much of the evidence documenting the prevalence and correlates of economic connectedness, or how connected low-income individuals are with high-income individuals, is from the United States. The causal evidence of economic connectedness to date either bundles economic connectedness with other associated goods (such as neighborhoods or classrooms), or analyzes the impacts of economic connectedness that happens through the randomization of peer groups, often in classrooms or dorm rooms.

⁴There remains a great need to find novel cost-effective mitigation strategies. Many of the interventions that positively impact mental health are either not cost-effective (see Haushofer and Salicath (2023) and Ridley et al. (2020) for a review) or explicitly target mental health disorders (Angelucci and Bennett, 2024; Bhat et al., 2022; Blattman et al., 2023; McKelway et al., 2023; Patel et al., 2007), which comes at the risk of low take-up or stigma (Pescosolido, 2013; Ridley, 2025; Smith, 2024).

⁵Empirically, economic research shows that homophily can hurt economies by stymieing the flow of information or goods (Burchardi and Hassan, 2013; Chaney, 2014), and can limit social cohesion (Rao, 2019). On the other hand, homophily can improve loan targeting and health adherence through reduced information asymmetries and improved trust (Alsan et al., 2019; Fisman et al., 2017).

valuable relationships with higher-income women, implying that income-based homophily is self-reinforcing.⁶

The paper proceeds as follows: Section 2 discusses the cultural context, Section 3 describes the experimental design, Section 4 presents first-stage results of the experiment (invitation-sending decisions), Section 5 presents treatment effects on second stage outcomes, Section 6 interprets the results through a conceptual model of social network formation, and Section 7 concludes.

2 Context

2.1 Rural Migration

This project is set in Mchinji, a rural district in Central Malawi. Eighty-five percent of my sample moved across rural villages for marriage, which separates women from their families and preexisting networks. Marriage migration is an exceedingly common phenomenon, especially for women. Women traditionally move to the area where her husband and his kin live (patrilocality) in 71% of societies (Murdock, 1967), and more societies have shifted towards patrilocality than away (Shenk et al., 2019).

In the 2015 Malawi Demographic and Health Survey, 57% of women in Mchinji lived outside their home village. This is a fairly representative district in Malawi—43% of the women in all other districts in Malawi lived outside their home village, though with regional variation (Appendix Figure A.1). Land ownership is an important predictor of moving villages, even conditional on ethnic and regional kinship norms (Appendix Table A.1).⁷ Overall, this sample is triply disadvantaged with regards to social inclusion on the basis of their gender, migrant status, and income status.

2.2 Correlates of Social Inclusion and Socio-Economic Status

I construct an index of socio-economic status, using proxies of household assets (a detailed description of how I construct the index is in Section 3.3.1). Importantly, the women who I code as ‘high-SES’ are poor on a global scale. On average, only 20% of them have a single household member who has completed secondary school, and they eat fewer than

⁶Furthermore, identifying a causal link between meat consumption and strategic social network investments adds context to the literature in development economics on nutritional poverty traps. A wide body of evidence finds that individuals consistently choose to spend excess income on foods that are expensive per calorie, rather than cheap calorie-dense foods, which has brought the nutritional poverty trap model into question (Dasgupta and Ray, 1986; Jensen and Miller, 2008; Subramanian and Deaton, 1996). I provide evidence that consuming expensive calories can be a rational *social investment decision* with substantial economic returns—in addition to being a health input or luxury consumption good.

⁷While the Chewa tribe, a predominant tribe in my sample, is traditionally matrilineal, norms have been largely disrupted and patrilocality is common even within traditionally matrilineal tribes.

three meals per day even right after the harvest (Appendix Table A.2). However, they are still significantly more advantaged than the women I code as ‘low-SES’, with almost double the landholdings, and almost double the likelihood of operating any business.

I find descriptive evidence that income is a social cleavage in my setting. Socio-economic status and years in the village are both positively and significantly correlated with measures of social inclusion, such as having more friends, being more likely to belong to a women’s church group, and reporting less loneliness (Figures A.2 and A.3). These measures improve with time in the village very slowly—women who have been in the village for twenty years have, on average, only one more friend than women who arrived this year—suggesting that frictions to social network linking may not resolve with time. Inclusion in economic relationships is also related to socio-economic status. Women in the top decile of socio-economic status are almost three times more likely to belong to a Village Savings and Loan Association (VSLA), an important source of credit in this setting, compared to women in the bottom decile (Figure A.3).

2.2.1 Baseline Networks

To elicit networks, enumerators ask participants to list each person with whom she engages with in a series of activities. At baseline, participants have six network connections (mean = 6.2, median = 6, IQR=2). These networks are split equally between relatives, usually from the husband’s side, and non-relatives, who the respondent usually did not meet through her husband. The most common activity to engage with network links in is meal-sharing, but usually with the husband’s family: at baseline, only 56% of women list any non-relative friend who they report sharing a meal with in the past year.

Baseline networks are homophilic with respect to income. In every village, participants with iron sheets roofs are more likely to link with other people with iron sheets roofs (a proxy for higher-income) than if they linked randomly within the village; and in all but four villages, participants with thatched roofs are more likely to link with other people with thatched roofs than if they linked randomly within the village (Figure 1).⁸

2.2.2 Depression and Loneliness

I measure depressive symptoms using the CESDR-10 (Center for Epidemiological Studies Depression Scale revised 10-item questionnaire). Consistent with convention, I denote anyone who scores 10 or greater as at risk of mild-to-severe depression. I measure loneliness using the UCLA-3 questionnaire, a three-item loneliness scale. Consistent with convention, I denote anyone who scores 6 or greater as at risk of loneliness. Among my

⁸Many of my respondents’ network connections are outside my sample, and I do not have detailed information about their household income. As an easily observable and salient income proxy, participants are able to report the roof material of each network connection.

Figure 1: Income-Based Homophily

sample of low-income migrant women, 27% are likely depressed at baseline and 14% are likely lonely. Although depression and loneliness are correlated, the correlation is quite weak ($\rho = 0.113$) and only 6% of the sample is both likely depressed and lonely.

Consistent with recent work documenting high levels of depression among the elderly in low- and middle-income countries (Banerjee et al., 2023), depression risk is starkly increasing in age (Figure A.4, left-side panel). Conversely, loneliness is U-shaped: the prevalence of loneliness is highest among the oldest and youngest deciles, and lowest in middle age.⁹ Surprisingly, while there is a significant correlation between the SES index and loneliness, there is *no correlation* between the SES index and depression.

There are two variables that emerge as predictors of both loneliness and depression: low food consumption and the difficulty of returning to a woman’s home village. Consuming on average three meals a day (38% of the low-SES sample) and having consumed any meat in the past month (77% of the low-SES sample) are each significantly associated with reductions in both depression and loneliness.¹⁰ I construct a PCA index of how challenging it is for a participant to return to her home village using the price of transport, time that a trip home takes, and visits home per year. This index is significantly correlated with both depression and loneliness, which reiterates the importance of migrant status to these women’s disadvantage (Figure A.4, right-side panel).

2.3 Meal-Sharing

Meal-sharing is a common social activity. At baseline, 90% of respondents report that they shared a meal with somebody outside their household in the previous week, with

⁹Twenty-three percent of the youngest decile (ages 18-20), versus 36% of the oldest decile (ages 42-69), experience depressive symptoms. Sixteen percent of women ages 18-20 and ages 42-69 experience loneliness, while the least lonely cohort is women ages 37-41, where 9% experience loneliness.

¹⁰The SES index is constructed from variables of productive assets and roof quality, rather than consumption, so these correlations are not mechanical.

68% of respondents both visiting and hosting somebody at least once. Participants report hosting others more often than visiting others, though both are common. For shared meals that participants host and shared meals where they visit others, it is equally common to go after being invited and to initiate a shared meal without an invitation.¹¹

Why is meal-sharing such a common activity? While *food*-sharing is a common method of risk-sharing, *meal*-sharing also encompasses sitting down together and eating with one another. In a sample of sixty-eight survey participants in rural Lilongwe (the district adjacent to Mchinji), I ask participants how personal a conversation could become across four settings: a shared meal, while working, while doing chores, and while at church. Both male and female participants overwhelmingly and consistently rate a shared meal as the setting where a conversation could become the most personal, regardless of if they imagine the shared meal to be with somebody who they typically share meals or with, or somebody they know from working together (Appendix Table A.3). Despite the high prevalence of meal-sharing, 72% of respondents report that they would prefer to share more meals per week than they shared last week (Appendix Figure A.5).

3 Experimental Design and Empirical Specifications

3.1 Sample

The intervention design is summarized in Figure 2. I recruit a sample of 3,600 women who moved to the village after 14 years old, no more than 20 years ago. During the recruitment Listing Survey, every eligible participant can add her name to a list of women who are interested in sharing meals with other women in the village more often (Sharing List), knowing that at a later stage some women in the village will see the list and have the opportunity to invite people from the list. Almost every woman signs up for the list (99.6%), and almost all agree to have their photo taken and displayed on the list so that women who do not know them by name can still send them an invitation (96.4%).

I use my listing sample data to construct geographic clusters and a continuous SES index, draw quintiles of the index within geographic clusters, and then assign women to high- or low-SES using these geographic-cluster-specific SES quintiles (SES index construction is described in Section 3.3.1). I randomly select 1,600 women from the bottom 80% of the SES index for the intervention (henceforth, the Intervention Sample), since high prices are more likely to be prohibitive for lower-income women. Of the women in the top 20% of the SES index, I offer 500 the opportunity to be a Guest. Of the women who are in the bottom 80% of the SES index, but are *not* selected for the Intervention Sample, I

¹¹Participants report that they hosted 2.3 meals and visited others for 1.6 meals in the past week on average. Anecdotally, shared meals that happen without an invitation are a result of visiting a friend in her home while she is cooking, and receiving a spontaneous invitation to join.

Figure 2: Study Design

Notes: Women are eligible for the Listing Survey if they are at least 18 years old, moved to the village after the age of 14, and have been there for fewer than 20 years. Geographic clusters are constructed using participant house coordinates from the Listing Survey and k-means clustering. Geographic clusters are based only on spatial proximity, and do not represent political or administrative boundaries. Women are coded as “Low-SES” if they fall below the 80th percentile on the SES-index within their geographic cluster, and are coded as “High-SES” if they are in the top quintile of the SES-index within their geographic cluster. The SES index is constructed using [Anderson \(2008\)](#) inverse covariance weighting of: household roof material, an indicator for if the woman lives in her own house, acres of land owned, and a business capital index. Low-SES women are randomly assigned to be in the Intervention Sample (N=1600); to be a Spillover Control group member (N=780); or to be a Guest (N=500). High-SES women are randomly assigned to be in the Spillover Control group (N=220), or to be a Guest (N=500). The Intervention Sample participate in every survey and constitute the main analytical sample in the paper. The Spillover Control Group and Guests are only surveyed in the Listing Survey and Endline, and Guests receive invitations during the Treatment Allocation Survey. The Intervention Sample is randomly split into Inviters (N=1200) and Control (N=400). Inviters are randomly assigned to have a Low-SES Guest List (they only view the names of Low-SES Guests on their Sharing List); a High-SES Guest List; or a Random Guest List (they view a mix of high- and low-SES women’s names). Conditional on being within 800 meters of the Inviter, conforming to the Guest List sub-randomization, and appearing on no more than ten lists total, six Guests are randomly assigned to each Inviter’s Sharing List. I cross-randomize a Voucher for a butcher across all Inviter treatments.

also offer 500 the opportunity to be a Guest. The women who sign up for the Sharing List *and* are randomly selected to be a Guest have the opportunity to actually appear on the Sharing List. The remaining participants serve as a Control group.

3.2 Treatment Arms

The RCT includes two intervention arms: an inviting service (“Inviter” treatment) and a meat price subsidy (“Voucher” treatment). The Inviter treatment includes information about who in the village would like to share meals, which reduces the believed probability

of rejection. Enumerators then send invitations for a shared meal on the participants' behalf, which reduces the true effort costs of sending invitations, such as the emotional costs of face-to-face rejection and the hassle of finding women in the village to invite.

The Intervention Sample, which is entirely low-SES, is randomized into three groups:¹²

1. Inviter Treatment (N=600): Participants view six names from the Sharing List and can invite zero to five of them to share a meal (invitation delivered by enumerators).
2. Vouchers + Inviter Treatment (N=600): Participants receive 7,000 MWK vouchers (about 4 USD), redeemable at a local butcher, and the Inviter Treatment.
3. Control (N=400): This group does not receive any intervention.

Within treatments 1 and 2, participants view one of three types of Sharing Lists: Low-SES Guest List (all women on the list are also in the bottom 80% of the SES index), High-SES Guest List (all women on the list are in the top 20% of the SES index), or the Random Guest List (names on the list are randomly selected across both the high-SES and low-SES subsamples). Respondents and enumerators are blinded to this sub-randomization, and are only informed that Guests are randomized to an Inviter's Sharing List based on proximity. There are 200 participants within each of the smallest subgroups (Figure 2).

The SES index is constructed from variables I collect in the Listing Survey, and has two advantages: because it is continuous, I can draw precise quantiles of income within villages and control the geographic saturation of High- and Low-SES women;¹³ and the Anderson (2008) weighting allows me to reward uncorrelated ways of holding wealth within a single index. Randomization is at the individual level, stratified by geographic-area clusters and quintile of the SES index. This stratification ensures that the density of the treatment arms does not differ spatially and create differential cultural shifts; and that average income differences between the Inviters and Guests are constant across treatment arms.

One at a time in a randomly assigned order of Inviters, I randomly select one Guest (among those eligible to appear on each specific Inviter's list) to appear on that Inviter's list. A Guest is eligible to appear for a specific Inviter if she conforms to the Inviter's treatment (for example, a high-SES woman cannot appear on the list of an Inviter randomized to see only low-SES Guest names), lives within 800 meters of the Inviter, and has not already appeared on ten lists. On average, Inviters report that they have spoken to 3.6 women on their list, and are significantly more likely to have previously spoken to

¹²I do not have a Voucher-only treatment arm in my study because I seek to test if, *conditional* on the access to initiate relationships with different sets of individuals, the price of meat serves as a barrier to social interaction. The Voucher treatment does not affect the probability of sending invitations, suggesting that fixed effort costs of social interaction, rather than financial costs, are the first-order constraint that inhibits women from initiating social relationships.

¹³The design requires precise portions of participants to be classified as High- and Low-SES, so we do not conflate the effects of cross- versus within-SES relationships with the effects of treatment saturation.

the women who live relatively closer to them.¹⁴

3.3 Data

I conduct four rounds of data collection: a Listing Survey with all 3600 participants (May 2024), a Treatment Allocation Survey with the Intervention Sample (July 2024), a Midline Survey with the Intervention Sample one month later (August 2024), and an Endline Survey with the full sample one year later after the following harvest (May 2025).

3.3.1 Listing Survey

The Listing Survey was conducted in May 2024. In this survey, all participants are informed that some people will be selected for a project where they might receive a voucher and the opportunity to invite other women to share a meal. Enumerators explain to participants that, while we cannot say if they will be selected for the program, they have the opportunity to put their name on a list that indicates their interest in receiving an invitation for a shared meal from a neighbor. They are informed that the list will not be printed, that it will only be used if at least ten women from within their area sign up, and that signing up for the list does not guarantee that they will receive an invitation or appear on a list.¹⁵ Enumerators then request to take a photo of the participant in front of her house, to help others identify her when they see her name on the list.

Defining Socio-Economic Status

I construct an index of socio-economic status from data collected in the Listing Survey. The SES index is the inverse-covariance-weighted index (Anderson, 2008) of the following variables: an indicator for having a high-quality roof material, an indicator for whether the respondent lives in her own home, acres of farmland owned, number of garden plots owned, and an index of business capital.¹⁶ There are two main classes of income-generating assets in this region: farmland and businesses. Land ownership serves as a proxy for farming assets, and I create a proxy for business capital based on the type of self-employment that each woman's household engages in.¹⁷

¹⁴See Appendix Section A.3 for more details about the Sharing List construction.

¹⁵Recall that signing up for the Sharing List does not guarantee that they are randomized to be a Guest. This clarification also ensures that Guests who do not receive an invitation are unaware that they ever appeared on any Sharing List. Since almost half of the women who sign up for the Sharing List do not participate in meal-sharing through the experiment, it is unlikely that women attribute non-participation to being excluded by Inviters, rather than by the experimenter. Qualitatively, women who do not participate in meal-sharing through the intervention attribute this exclusion to random group assignment rather than to exclusion by the community.

¹⁶See Appendix Section A.1 for a detailed description of how I construct the business capital index. To account for cases where roof material is not one's own asset (for example, staying with relatives while the home is under construction), I include a variable indicating if the respondent lives in her own home.

¹⁷I use the Anderson (2008) index because it down-weights correlated variables, rewarding both the stock and the diversity of assets.

I code women in the top 20% of the SES index as high-SES (quintiles drawn within geographic clusters), and women in the bottom 80% of the SES index as low-SES. Note that these women are *relatively* lower- and higher-income than one another, but are still all very poor on a global scale, and even within the context of Malawi. That said, there are still stark differences between the high- and low-SES samples (Appendix Table A.2).

Since participants have network connections who are outside the sample, for whom I do not have data, I cannot use the SES index to measure the income of participant’s network. Roof material is an observable household feature, and a salient income proxy. I ask participants to report the roof material for each network link, and use the composition of the roof material of network ties as a proxy for network economic connectedness. While roof material is a coarse proxy, and is not as good at identifying the highest-income individuals because 38% of the sample has a higher-quality roof, it approximates the high- and low-SES sub-samples within my sample fairly well (Appendix Table A.2).

3.3.2 Treatment Allocation Survey

The Treatment Allocation survey was conducted in July 2024. Women are randomized into treatment groups using a computer program after the Listing Survey. Women in the Intervention Sample all participate in the Treatment Allocation survey. First, women are informed if they are recipients of the Voucher treatment. After receiving their Voucher treatment status, women in the Inviter treatment see a list of up to six names and photos and receive the opportunity to send invitations to up to five women on the list.

I use the following three comparisons to test for baseline balance: all Inviters versus Control participants in the Intervention sample (Appendix Table B.1), Inviters with the High-SES Guest List versus Inviters with the Low-SES Guest List (Appendix Table B.2), and Inviters with the Random Guest List and the Voucher versus Inviters with the Random Guest List without the Voucher (Appendix Tables B.4).¹⁸ Across all three of these tests, two unbalanced variable emerges: the Inviters with the Low-SES Guest List are rent more garden plots than Inviters with the High-SES Guest List (0.170 SD difference), and Inviters with the High-SES Guest List are more likely than Inviters with the Low-SES Guest List to name their husband in their baseline network (0.068 SD difference) (Appendix Table B.2). Thus, in all specifications, I control for these two variables.¹⁹

¹⁸I present comparisons of all other sub-groups in Tables B.2 and B.3 for completeness. To avoid over-fitting, I limit my the balance tests that I use to select control variables to the three main comparisons that I use in analytical inference.

¹⁹Reassuringly, this imbalance goes in the opposite direction of treatment effects. Inviters with the High-SES Guest List, the group with fewer baseline garden plots, improve more in their food security. Inviters with the Low-SES Guest List, the group less likely to socialize with their husbands at baseline, are suggestively the most likely to improve in their marital relationships. Controlling for these unbalanced variables, women who actually share meals are also balanced on all other variables across all groups (Appendix Table B.7), reaffirming that it is very unlikely that selection on these variables drives results.

3.3.3 Midline and Endline Surveys

I collect outcome data one month after the Treatment Allocation Survey in a Midline Survey (August 2024, with the Intervention Sample only), and one year after the Treatment Allocation Survey in an Endline Survey (May 2025, with the full sample).

Main Outcomes

I analyze three primary downstream outcomes: a food security index, total farm yields in USD value, and an indicator for experiencing mild-to-severe depressive symptoms.²⁰

Food Security Index: The food security index is the first PCA component of the typical number of meals participants eat daily and the frequency of animal protein consumption. Food and protein consumption are both particularly consequential in this sample, 50% of whom report pregnancy, child-birth, or breast-feeding during the intervention. Variables in the midline food security index are estimated over the past month, and I exclude meat consumption because it is mechanically affected by the Voucher treatment. One year later, a positive shock to consumption during the “lean season”—the annual period of lowest consumption, which falls between the midline and endline surveys—is potentially more welfare-enhancing than over the past month because it has implications for consumption-smoothing. Bearing in mind the value of food security in the population broadly, and the augmented importance of food security in the lean season, the one-year food security index incorporates measures of the frequency of daily meals and the frequency of consuming animal proteins (including meat), both in the past month and during the lean season (more details about variable definitions are in Appendix Section A.4).

Farm Yields in USD Value: Respondents self-report their yields for each crop, estimating their expected yields if they have not finished harvesting all of their crops (the endline survey overlaps with the end of the harvest). Participants report yields in the unit of measurement that they harvest each crop, and I convert their total yields into kilograms. Then, for the most frequently cultivated crops—maize, beans, groundnuts, soybeans, sunflower seeds, tobacco, sugarcane, pumpkin, and sweet potatoes—I multiply their total harvest by the market rate per kilogram in USD, as reported by local news articles. I only collect this outcome in the Endline Survey, since there is an annual harvest and the Midline Survey was before the agricultural season.

Mild-to-Severe Depressive Symptoms: I measure depressive symptoms using the CESDR-10 tool (Center for Epidemiological Studies Depression Scale revised 10-item questionnaire). Consistent with convention, I denote anyone who scores 10 or greater as at risk of depression. Consistent with convention, “Mild depressive symptoms” is a score from

²⁰See Appendix Section E.1 for explanations of deviations in main outcomes from the Pre-Analysis Plan, and a populated Main Outcomes table as described in the Pre-Analysis Plan.

10-15; “Moderate” is a score from 16-21; and “Severe” is a score of at least 22.

Network Elicitation

I elicit networks by asking participants to report the names of each person with whom they engage in a series of economic and social activities. For each network link, I ask respondents details about their relationship. The first time that they report a given network tie, I ask a series of objective questions about each link that are likely to remain dynamically stable: their ethnicity, religion, household roof material, marital status, and proximity in walking time. In each survey round where a respondent names someone in the network, I ask her to report two objective facts about the relationship—how often they see each other, and if they most typically see each other in groups or alone—and five subjective questions, which I use to define “strength of ties”.

Strength of Ties: For each network link that I elicit, I collect data about the respondent’s subjective experience in that relationship. I use these variables to measure “strength of ties”. There are five variables that enter the “strength of ties” index, capturing trust, humor, closeness, and reciprocity (questions described in Appendix Section A.4).

I conduct a PCA analysis of these five variables across all ties (at the dyad level) in the Listing Sample. I use the first principal component to construct weights that I then apply to these five variables across all following surveys. This method applies the baseline levels and correlation structure of these five variables to analyze strength of ties in following survey rounds, so that the definition of “strong ties” remains fixed. Furthermore, this method allows me to conduct a levels comparison in strength-of-ties over time.

In order to identify the ties that are the strongest, and most clearly represent something like a “best friend”, I define “strong ties” as ties whose strength-of-ties index is equal to the maximum (6.2% of baseline ties; 13% of midline ties; and 17% of endline ties). I also analyze ties both above and below the baseline median on the strength-of-ties index (“weak ties” and “mid-strength ties” for simplicity of exposition).

3.4 Estimating Equations

3.4.1 First Stage

First I evaluate Inviters’ decisions about who to invite using the following specification:

$$I_i = \beta_0 + \beta_1 T_i^{R,V} + \beta_2 T^{H,NV} + \beta_3 T^{H,V} + \beta_4 T^{L,NV} + \beta_5 T^{L,V} + X_i + \delta_i + \gamma_i + \epsilon_i \quad (1)$$

where I_i takes the value of 1 if Inviter i sends an invitation to any Guest, and 0 otherwise; T_i indicates treatment groups (Random Guest List with Voucher, High-SES Guest List without Voucher, High-SES Guest List with Voucher, Low-SES Guest List without

Voucher, and Low-SES Guest List with Voucher); X_i is a vector of unbalanced baseline controls and lasso-selected controls, δ_i are wealth-quintile fixed effects, and γ_i are geographic cluster fixed effects (my two randomization strata). I use heteroskedasticity-robust standard errors. For regressions concerning invitation-sending, Inviters with the Random Guest List without the Voucher are the omitted group.

Next, I conduct several analyses to understand the composition of the Guests that Inviters select. The following specification is restricted to the sample of Inviters with the High-SES Guest List or the Random Guest List:

$$I_i^H = \beta_0^H + \beta_1^H T_i^{R,V} + \beta_2^H T_i^{H,NV} + \beta_3^H T_i^{H,V} + X_i + \delta_i + \gamma_i + \epsilon_i \quad (2)$$

where I_i^H takes the value of 1 if Inviter i sends an invitation to a High-SES Guest, and 0 otherwise. The next specification is restricted to Inviters with the Low-SES Guest List or the Random Guest List:

$$I_i^L = \beta_0^L + \beta_1^L T_i^{R,V} + \beta_2^L T_i^{L,NV} + \beta_3^L T_i^{L,V} + X_i + \delta_i + \gamma_i + \epsilon_i \quad (3)$$

where I_i^L takes the value of 1 if Inviter i sends an invitation to a Low-SES Guest, and 0 otherwise.²¹ Finally, using only Inviters with the Random Guest List, I estimate:

$$I_i^{H\&L} = \beta_0^{H\&L} + \beta_1^{H\&L} T_i^{R,V} + X_i + \delta_i + \gamma_i + \epsilon_i \quad (4)$$

where $I_i^{H\&L}$ takes value 1 for Inviters who send an invitation to at least one High-SES Guest and at least one Low-SES Guest.

3.4.2 Second Stage: Intent-to-Treat Results

To estimate the intent-to-treat treatment effects of the intervention on second-stage outcomes, I conduct the following analysis:

$$Y_i = \beta_0 + \beta_1 T_i^{R,NV} + \beta_2 T_i^{R,V} + \beta_3 T_i^{H,NV} + \beta_4 T_i^{H,V} + \beta_5 T_i^{L,NV} + \beta_6 T_i^{L,V} + Y_{BL,i} + X_i + \bar{S}_i + \delta_i + \gamma_i + \epsilon_i \quad (5)$$

where Y_i is an outcome variable, T_i denotes the treatment group, $Y_{BL,i}$ is the baseline measure of the dependent variable (following [Cilliers et al. \(2024\)](#)), X_i is a matrix of lasso-selected controls and unbalanced baseline variables, δ_i are wealth-quintile fixed effects, and γ_i are geographic cluster fixed effects. When testing second-stage outcomes, the omitted group is always the Control group.

There is the potential for SUTVA concerns with this experiment. When an Inviter shares

²¹Mechanically, for Inviters with the Low-SES Guest List, $I_i^H = 0$, and $I_i^L = I_i$. Mechanically, for Inviters with the High-SES Guest List, $I_i^L = 0$, and $I_i^H = I_i$.

a meal with a Guest, the Inviter or Guest might reduce meal-sharing with their other neighbors, including Control participants, which would bias treatment effects upwards. Conversely, when an Inviter shares a meal with a Guest, Control participants who are friends with the Guest or the Inviter might be included in these meals and new friendships, biasing treatment effects downwards.

In Equation 5, $\bar{S}_i$ is a vector of four control variables that account for exposure to spillovers: the total number of surrounding Inviters and Guests; the total number of Inviters with the Low-SES Guest List plus Low-SES Guests; the total number of Inviters with the High-SES Guest List; and the total number of High-SES Guests. The first measure establishes the effect of the treatment as a whole. The second measure establishes the effect of being exogenously surrounded by within-SES relationships. The third and fourth measures establish the effect of be exogenously surrounded by cross-SES relationships, separately by proximity to the low-SES and high-SES sides of the link. I include each of these measures since the direction of potential bias on the treatment effects depends on the nature of the relationship. For each spillover measure, I estimate $\bar{S}_i$ by counting the number of participants of interest within fifty meters, and then recentering the variables to account for endogenous spatial variation following [Borusyak and Hull \(2023\)](#).

4 Results: First Stage

4.1 Invitation Sending Across Treatment Sub-Groups

First, I analyze Inviter’s invitation-sending decisions in the experiment. Control participants did not have the opportunity to send any invitations, so I use Inviters with the Random Guest List without the Voucher as a comparison group for all other sub-treatments. Eighty-one percent of Inviters invite at least one Guest, and the rate is not different across treatment arms (column (1) of Table 1). Inviters invite 1.4 Guests on average (1.8 Guests among Inviters who invite anyone) (Appendix Table C.1). The vast majority of these invitations are to women who are not in participants’ baseline networks, indicating that effort costs of social linking are prohibitively high, yet easy to overcome with a simple intervention. Furthermore, I cannot rule out that there are *no differences* in the effort cost that a low-SES woman bears in sending an invitation to a low-SES versus a high-SES woman.

In all of the Inviter treatment arms, there are no differences in the probability of sending an invitation with or without the voucher, suggesting that serving a low-quality meal to either a high-SES or low-SES woman is still better than nothing. However, evaluating Inviters with the Random Guest List elucidates that the Voucher *does* have a treatment effect on the composition of invitations.

Table 1: Treatment Effects on Invitation-Sending to Low-SES and High-SES Guests

	(1)		(2)		(3)		(4)	
	Invites Any Guest		Invites Low-SES Guest		Invites High-SES Guest		Invites Both

Test: <i>HSES without V = HSES with V = LSES without V = LSES with V</i>					[p= 0.432]			
DID Estimates [P-values]								
High-SES without Voucher – Low-SES without Voucher					0.052	[p= 0.403]		
High-SES with Voucher – Low-SES with Voucher					-0.002	[p= 0.977]		
Random with Voucher:								
(1) Invites High-SES – Invites Low-SES					0.073	[p= 0.270]		
(2) Invites Both – Invites Either Type			0.094	[p= 0.020]	0.021	[p= 0.628]		

Standard errors in parentheses

All specifications include baseline unbalanced control variables (moved to the village for marriage), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. Any Guest (column 1) indicates if the Inviter sent an invitation to at least one Guest. Low-SES Guest (column 2) indicates if the Inviter sent an invitation to at least one low-SES Guest (Inviters with the High-SES Guest List did not see any low-SES names, so this outcomes is mechanically zero for this group). High-SES Guest (column 3) indicates if the Inviter sent an invitation to at least one high-SES Guest (Inviters with the Low-SES Guest List did not see any high-SES names, so this outcome is mechanically zero for this group). Invites Both (column 4) indicates if the Inviter sent at least one invitation to a High-SES Guest, and at least one invitation to a Low-SES Guest.

* $p < .1$, ** $p < 0.05$, *** $p < 0.01$

Inviters with the Random Guest List invite Low-SES Guests and High-SES Guests at the same rate without the voucher (53% and 53.5% of the time, respectively), suggesting that there is heterogeneity in who Inviters prefer to interact with. Furthermore, inviting *both* is the most popular option. Among Inviters with the Random Guest List without the Voucher, 23.5% of respondents invite both, twice as common as selecting two-or-more low-SES Guests or high-SES Guests (selected 9.5% and 10.5% of the time, respectively), and more common than selecting one low-SES or one high-SES Guest (selected 20.0% and 19.5% of the time, respectively) (Appendix Table C.3). This already is highly suggestive that women value economic diversity among the people with whom they interact.

The Voucher induces a 10.5 percentage point increase (45%, $p < 0.05$) in inviting both, driven entirely by increased invitations to High-SES Guests (Table 1). This comes without a reduction in the probability of inviting Low-SES Guests, and is accounted for entirely by women who would have only invited Low-SES Guests without the voucher, who are induced by the voucher to *also* invite a High-SES Guest.²² This pattern reveals that

²²Women who otherwise would have invited one low-SES Guest are more likely to invite one Low-SES Guest and one High-SES Guest; and women who otherwise would have invited multiple Low-SES Guests are more likely to substitute one of those invitations for a High-SES Guest (Appendix Table C.3).

high prices constrain cross-SES relationships because of substitution with within-SES relationships. By revealed preference, cross-SES relationships are *relatively* more valuable at higher levels of financial investment, but not at the expense of within-SES relationships.

4.2 Meal-Sharing Across Treatment Sub-Groups

While 81% of Inviters invite at least one Guest, 45% of Inviters share a meal with a Guest within one month, and 60% share a meal within one year. Meal-sharing rates are statistically indistinguishable across Inviter groups with High-SES and Low-SES Guests (Appendix Table C.4), suggesting that the effort costs of meal-sharing itself, like the effort costs of sending an invitation, are not systematically higher for cross-SES matches.

The rate of meal-sharing is higher for Inviters with the Random Guest List with the voucher. This is largely driven by increases in meals with high-SES Guests, but I cannot rule out that this increase is no different from a small increase in meals with low-SES Guests. This increase occurs only when agents can choose across types and afford higher-quality meals, suggesting a complementarity between selection and investment.

4.3 Long-Term Relationships

While the extent of the intervention is to directly encourage women to send invitations for a shared meal, it is crucial to understand the implications of these invitations beyond the first shared meal to interpret the effects of the intervention. At endline, the majority of Inviters report that they saw at least one Guest in the past month, and these are often intentional interactions rather than chance encounters. Twenty percent of Inviters and 16% of Guests report that they have a strong or deep relationship with at least one Guest or Inviter.²³ In open-ended responses describing experiences with the intervention, 65% percent of Inviters and 65% of Guests mention a keyword describing positive emotions, learning opportunities, and support (Table 2).²⁴ The intervention creates positive interpersonal experiences, where women share information and express happiness to spend time with each other. Furthermore, a non-trivial portion of these experiences lead to persistent and mutually meaningful friendships.

Are these relationships marginal, or do they crowd out relationships that would have formed without the intervention? While the number of people that participants report doing activities with is not affected by the Inviter treatment, *who* is in the network changes. Among all Inviters there is a significant increase in “network churn”, defined

²³At endline, participants describe their experiences with each invitation that they sent or received in open-ended responses. In Appendix Section A.5, I list the key phrases I use to determine what a close relationship is, such as “we talk often” and “we are still friends”.

²⁴If I omit the keywords “share” and “sharing”, to remove mechanical discussion of meal-sharing, 52% percent of Inviters and 47% of Guests mention any of the other positive keywords.

Table 2: Text Response Analysis: Keyword Counts

Theme	Keywords	N: Inviters	N: Guests
Positive Emotions	trust, happy, love, warm, welcome, respect	253 (22%)	187 (19%)
Information Diffusion	info, learn, idea, teach, taught	299 (26%)	207 (21%)
Mutual Support	encourage, support, lend, borrow, help	279 (24%)	235 (24%)
Share	share, sharing	501 (44%)	450 (47%)

Notes: In the endline survey, enumerators ask Inviters about their experience with each Guest who they sent an invitation to; and ask Guests about their experience with each Inviter who they received an invitation from. Enumerators also ask all respondents about their overall opinions of the program. I conduct a simple keyword search from these text responses. Column (3) (“N: Inviters”) is the number of Inviters who ever use one of the keywords in column (2) (“Keywords”) across any of these text response questions. Column (4) (“N: Guests”) is the number of Guests who ever use one of the keywords in column (2) (“Keywords”) across any of these text response questions.

as the sum of baseline ties that are absent from the follow-up network and ties in the follow-up network that were not present in the baseline network (Appendix Table D.11).²⁵

This network churn is driven by Inviters dropping weak ties present in the baseline network and replacing them with other weak ties (Appendix Table D.12 and D.13). There is a small but precise increase in new strong ties, without any change in the probability of dropping baseline strong ties. I find suggestive evidence that networks change so as to increase the presence and strength of women’s own friends in the network, with modest reductions in the presence and strength of relatives in the network, particularly those that are on the husband’s side of the family (Appendix Tables D.14 and D.15). This shift away from interacting with husband’s relatives, and towards women’s own friends, is driven by specific activities: lending, secret-sharing, and advice-seeking (Appendix Tables D.16, D.17 and D.18).²⁶

5 Results: Second Stage Outcomes

I evaluate the effect of the intervention on three main outcomes: food security, farm yields, and depression. These outcomes capture both the instrumental return that relationships can provide and the intrinsic benefits of companionship.

Pooling all Inviters, the Inviter treatment leads to a 0.129 standard deviation increase in food security ($p < 0.05$); a 0.077 percentage point reduction in depressive symptoms (22%, $p < 0.01$); and no distinguishable impact on farm yields (Table 3). The farm yields measure is extremely noisy, with the 95% confidence interval spanning a 13% reduction

²⁵There is also network churn specifically among meal-sharing ties (Appendix Tables D.19).

²⁶This set of results helps clarify why my main treatment effects are inconsistent with the “rotten kin” literature, which shows that social pressure to share income can distort investment and labor supply decisions (Carranza et al., 2022; Dillon et al., 2021; Jakiela and Ozier, 2016; Swanson, 2025). Contrarily, I find that relationships built specifically by sharing resources can improve investment, savings, and business decisions. The shift in activities (including lending) away from extended family networks and towards own friends suggests that the intervention may allow participants to rely *less* on “rotten kin”, and that relationships built on resource-sharing need not imply extractive obligations.

to an 18% increase in the value of farm yields, but I highlight the outcome because farm yields are the most important income-earning opportunity in the year. Other income-earning opportunities primarily serve as a means to liquidity outside of the harvest season and protection from shocks.²⁷

The effects on food security are larger among Inviters with the High-SES Guest List than Inviters with the Low-SES Guest List (DID: 0.142 SD, $p = 0.026$), while the treatment effects on depressive symptom reductions are larger among Inviters with the Low-SES Guest List than Inviters with the High-SES Guest List (DID: -0.062 percentage points, $p = 0.035$). Treatment effect estimates among Inviters with the Random Guest List lie between the other two groups on both outcomes.

Many agricultural economies experience seasonal variation in food supply and prices, creating a phenomenon where agents consume less food during the high-price “lean season”. The endline increase in food security is driven by increases in animal protein consumption in any time period, and increases in the typical number of daily meals consumed during the lean season (Appendix Table D.1). The endline survey is conducted towards the end of the harvest season, so the fact that there is no detectable change in farm yields is consistent with the fact that there is likewise no change in the typical number of daily meals consumed in the past month.²⁸

While the depressive symptom reductions may be related to food security increases, food security cannot be the primary mechanism through which the Inviter treatment improves mental health. The group that experiences the largest depressive symptoms reductions experiences the smallest food security gains, and vice versa. Benchmarking the magnitudes of the effects on depressive symptoms against cash and asset transfer programs, which intervene on income rather than on social connection, my impacts are almost twice as large (Ridley et al., 2020).²⁹

In Sections 5.1 and 5.2, I evaluate potential explanations for how these social relationships lead to such large economic and psychological improvements, and why different types of relationships are more impactful across different outcomes. While I present results pooled and for all sub-groups, I rarely analyze or interpret differential Voucher effects,

²⁷Eighty percent of participants report cultivating agriculture and 25% report earning income through self-employment. Among Control participants who earn through agriculture and self-employment, the value of their harvest yields are more than four times the self-employment profits in the past year.

²⁸There is a development economics literature evaluating ways to smooth seasonal variation in food security, which has largely focused on heavy-handed financial interventions (Dillon, 2021; Stephens and Barrett, 2011; Fink et al., 2020; Basu and Wong, 2015; Burke et al., 2019). Consistent with Augenblick et al. (2024), which finds that a simple psychological budgeting exercise can increase lean-season liquidity, I find evidence that little more than a nudge (peer-to-peer information-sharing and relationship-building) can generate new lean-season income streams, and that high-cost programs may not be necessary.

²⁹Ridley et al. (2020), which averages the effects of twenty-eight cash transfer and multifaceted anti-poverty programs, find a 0.094 SD improvement in mental health, whereas I find an improvement from 0.16 SD (pooled estimate) to 0.23 SD (Inviters with the Low-SES Guest List).

Table 3: Treatment Effects on Main Outcomes

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. The Food Security Index (columns 1 and 2) is a PCA index in standard deviations from the Control mean. The Food Security Index at 1 Month is a PCA index of: the typical number of meals consumed per day in the past month, and the number of meals with fish or eggs consumed in the past month. The Food Security Index at 1 Year is a PCA index of: the typical number of meals consumed per day in the past month, and the number of meals with meat, fish or eggs consumed in the past month, the typical number of meals consumed per day during the lean season, and the number of meals with meat, fish or eggs consumed during the lean season. To calculate the Farm Yields in USD value (column 3), households estimate their harvest yields for each crop. I multiply market rates in agricultural reports by yields for the most high-yield crops: maize, soy beans, groundnuts, beans, tobacco, sugar cane, sunflower seeds, sweet potatoes, and pumpkin. Depression is calculated using the CESDR-10, a 10-item revised version of the Center of Epidemiologic Studies Depression Scale. (columns 4 and 5) indicates a score greater than or equal to 10.

since the first-stage is largely equivalent across the Voucher sub-treatments. I correct for multiple hypothesis testing across thirty hypotheses in Appendix Table E.4, and almost every statistically significant result from the main analysis remains significant at the 90% confidence level using False Discovery Rate-sharpened q-values (Benjamini et al., 2006).

5.1 Instrumental Utility

What allows women to consume more meals per day during the lean season, and more protein throughout the year? I explore several potential mediators, and identify two persuasive explanations: improved productive time use and reduced lending increase liquidity, and risk mitigation increases the option value of consumption during the lean season. I find no changes in borrowing or intra-household bargaining (Appendix Table D.9 and Table D.10). In Appendix Section D.0.1, I present evidence for channels for which I find suggestive evidence, but do not have the data to make conclusive statements.

5.1.1 Improved Productive Time Use

Aside from agriculture, households earn income through piecework and self-employment. Piecework, which 63% of Control households participate in at some point during the study period, constitutes supplying labor on a task-by-task basis to farmers with larger land-holdings. Self-employment, which only 27% of Control households earn income from in the study period, constitutes selling goods and services around the village or in a market.³⁰ Self-employment provides an alternate stream of liquidity, has the potential for much higher earnings than piecework, and requires less physical exertion.

There is no increase in piecework in employment in any treatment group (Appendix Table D.5), but there is evidence of a reduction in piecework search frictions. Workers search for jobs each time they need liquidity, and Control respondents report searching for piecework without finding it on average three days per month. Inviters spend fewer days searching unsuccessfully for piecework, which may free up time or energy for other productive activities (Table 4).

One such productive activity is self-employment. At endline, Inviters with the High-SES Guest List, who experience the largest improvements in food security, are 5.5 percentage points (20%, $p < 0.10$) more likely to earn income through self-employment in the past year than the Control group. Inviters with the High-SES Guest List enter self-employment immediately after the experiment begins. In the midline survey, only one month after enumerators send meal-sharing invitations to High-SES Guests, these Inviters are 9.2 percentage points (51%, $p < 0.01$) more likely to earn income through self-employment

³⁰The most common self-employment activities involve selling simple consumables (most frequently, “selling prepared foods”), and 70% of self-employed women sell only to customers around the village.

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. (columns 2 and 3) is the average number of days the participant reports typically searching for piecework in a month, but not finding it. Column (2) is the average number of idle search days per month during the growing season (the agricultural season largely overlapping with the lean season), and Column (3) is the average number of idle search days per month during the harvest season. (columns (4)-(6)) takes the value of 1 if the participant engaged in self-employment, i.e. the sale of goods or services, to earn income. Column (4) indicates earning income from self-employment any time in the past year, whereas columns (5) and (6) indicate earning income from self-employment in just the past month, measured at different times.

than Control participants. There are modest increases among Inviters with the Random Guest List, commensurate with smaller but still positive food security effects.

These effects are largely driven by women entering self-employment for the first time, and many of them directly copy the self-employment activities of a high-SES Guest (Table D.4).³¹ Next, I investigate potential explanations for how one shared meal leads women to diversify their income streams within just one month. I argue that the most likely explanation is information diffusion from high- to low-SES women.

Information Drives Self-Employment Entry

High-SES women might share valuable information about entering self-employment in these meals. This explanation is consistent with the “strength of weak ties” theory (Granovetter, 1973), which argues that weak non-homophilic ties are precisely those that bring in novel information (recall that the experiment leads to more churn among weak links in the network). Most of the self-employment activities that participants engage in do not require formalization nor a physical business space (for example, selling baked goods to other villagers). Consequently, the fixed capital costs of entering self-employment are low, and information may be enough to help women overcome barriers to entry. When asked to explain why they chose to invite the Guests they selected, Inviters with the High-SES Guest List are more likely than either of the other groups to say that it was because their guests are knowledgeable (Appendix Table C.7). Furthermore, at midline, Inviters with the High-SES Guest List are more likely to say that they discussed ways to find business resources in their shared meals (Appendix Table C.8).³²

For participants whose household enters into any new self-employment activity in the past month by midline, I ask them why they entered into this activity. New information emerges as a key reason: The most common reason respondents give for earning from a new self-employment activity is that “somebody told me this is profitable” (45%), and five percent of women say that they received training.³³

Borrowing Does Not Explain Treatment Effects on Self-Employment Entry

Twenty-one percent of respondents report that they enter into a new self-employment activity because somebody helped them to find capital, suggesting that fixed costs are an important constraint. However, Inviter borrowing rates are not different from Control.

³¹I define copying self-employment activities as an Inviter who sells a good or service for the first time that a Guest on the Inviter’s list reports selling at *baseline*.

³²If participants have already shared a meal with their Guest at the midline survey, I ask them to report the conversation topics that they discuss with each Guest. Inviters with the Low-SES Guest List are more likely to discuss marriage, romantic relationships, and ways to find piecework.

³³This is consistent with a literature on peer effects in entrepreneurship, which finds an important role for social networks in the diffusion of information and business practices (Asiedu et al., 2025; Cai and Szeidl, 2017; Fafchamps and Quinn, 2018; Hardy and McCasland, 2021; Vega-Redondo et al., 2019).

While capital inputs matter for starting new self-employment activities, information is the more binding constraint that high-SES social ties effectively resolve.

Market Linkages Do Not Explain Treatment Effects on Self-Employment Entry

Guests referrals to suppliers, customers, or business contacts cannot fully account for the large and persistent increase in self-employment activity. While 18% of respondents who start a new self-employment activity say at midline that they entered into this activity because they found customers, only 8% of participants who ever engage in self-employment report having any stable business relationships (for example, regular suppliers or customers), with no differences between Inviters and Control.

5.1.2 Reduced Lending

Inviters across all sub-treatments report lending money or goods to fewer people in the past year than Control, which may be in part responsible for having the liquidity for more food consumption (Appendix Table D.21). This is driven entirely by a reduction in lending to baseline network members and husband’s relatives (Appendix Table D.17). Inviters lend less to the same people who they lent to the previous year, and are less likely to give loans for the first time to members of the baseline network. There is actually an *increase* in the number of borrowers who are new to the network, but this is more than offset by the reduction in the number of baseline network-members to whom they lend, leading to an overall decrease in the number of borrowers.

The reduction in borrowers is explained by weak- and medium-strength ties, while the number of strong ties who Inviters lend to is unaffected (Appendix Table D.20).³⁴ Consistent with a reshaping of risk-sharing networks, Inviters borrow from more people who are new to the network, and from fewer people who they listed in their baseline networks, even though the total number of people or amount of borrowing does not change (Appendix Table D.22).

5.1.3 Reduced Risk of Lean Season Consumption

Inviters Diversify Their Crop Portfolios

Inviters undertake a striking transformation in their agricultural production function by diversifying their crop portfolios, reducing the risk they face during the lean season associated with the upcoming harvest. Inviters’ primary method of crop diversification is

³⁴Inviters report that they have more network members who they would feel very comfortable to lend to, indicating that the reduction in borrowing is not driven by a decrease in willingness to lend broadly speaking, but instead a decrease in lending to people who they are uncomfortable lending to (Appendix Table D.7). Compared to Control, Inviters reduce lending to their husbands’ relatives but not their own friends, suggesting that this pattern is more likely explained by Inviters foregoing “kinship taxes” altogether, rather than Inviters replacing friends who need loans with friends who do not need loans.

to diversify the *types* of crops that they cultivate. I consider five classes of crops: maize (the staple grain), other starches, fruits and vegetables, legumes, and cash crops.³⁵ The probability that Inviters grow crops from at least three of these classes increases by 4.7 percentage points (54%, $p < 0.01$) (Table 5). This implies that Inviters are less vulnerable to environmental or market shocks that affect any single crop *or* any single class of crops.

All Inviters are more likely to grow fruits and vegetables, while Inviters with the High-SES Guest List are more likely to grow cash crops (Appendix Table D.6). The value of cash crop yields increases among Inviters with the High-SES Guest List by 30 USD (12% of the Control mean, $p < 0.05$), with a noisy off-setting reduction in the value of subsistence crop yields (a 31 USD reduction, which is a 10% decrease over the Control mean that is not statistically distinguishable) (Table 5).

Inviters Report Financially Reliable Network Relationships

If Inviters have network ties that they are confident they can rely on in case of a negative shock, they may be more comfortable consuming rather than saving. I create a PCA index of “potential for risk-sharing” using variables denoting subjective comfort risk-sharing with network ties and participation in organized risk-sharing groups. In Table 6, I report the Potential for Risk-Sharing index and two representative variables entering the index.³⁶ Among Inviters with the High-SES Guest List, the Potential for Risk-Sharing index increases by 0.105 SD ($p < 0.10$). The index is not significantly different from Control among Inviters with the Random Guest List, but this masks Voucher-level heterogeneity. The index increases among Inviters with the Random Guest List and the Voucher by 0.183 SD, which is statistically distinguishable from Control ($p < 0.05$), and from Inviters with the Random Guest List without the Voucher ($p < 0.05$).

There are two narrow groups of Inviters who say they would be very comfortable borrowing and lending with more people in their networks: Inviters with the High-SES Guest List and the Voucher, and Inviters with the Random Guest List and the Voucher. Though not definitive, when households have exogenous access to high-SES links, they might use the Voucher to mitigate their vulnerability to shocks by establishing relationships with financially reliable ties. Indeed, Inviters with the Voucher (pooled across all three groups) are more likely than Inviters without the Voucher to say the reason they selected the Guests they invited is because they are generous (Appendix Table C.6).

Inviters are 26% more likely to join “Welfare Groups” ($p < 0.10$, Table 6), home-grown self-help groups that are not operated by any formal institution. The most common of these groups functionally operates like informal health and life insurance.³⁷ This increase

³⁵More details on how I classify crops are in Appendix Section A.4.

³⁶I report the other variables entering the index in Appendix Table D.7.

³⁷See Section D.0.1 for details on how ‘Welfare Groups’ operate.

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. The (columns (1) and (2)) is a PCA index of variables subjective comfort risk-sharing in the network and participation in organized risk-sharing groups. Variables of subjective comfort risk-sharing in the network are: the number of people in the network the participant feels very comfortable lending to; the number of people in the network the participant feels very comfortable borrowing from; and the number of people in the network the participant feels very comfortable both borrowing from and lending to. Variables of participation in organized risk-sharing groups are indicators for participation in each of the following: welfare groups (endline only), ROSCA, and VSLA. For each network tie, participants report their comfort in borrowing from or lending to that person on a Likert scale. The outcomes in columns (3) and (4) report the number of those friends for whom that participant said she would be with both lending and borrowing. , the outcome in column (5), is an indicator for if the respondent reports being in a home-grown self-help group, where the most common version is a mutual-insurance scheme. Other common groups involve methods of pooling resources for group purchases.

is driven by Inviters with the Random Guest List and the Voucher, who are 63% more likely to be Welfare Group members ($p < 0.01$).

5.2 Intrinsic Utility

The Inviter treatment leads to a very large reduction in mild-to-severe depressive symptoms, driven by a reduction in mild depressive symptoms, which is significantly more common than moderate or severe depressive symptoms (Table D.3). While still clinically relevant, less severe forms of depression may not require professional intervention, and are plausibly treatable with social support. Treatment effects on every question in the CESDR-10 questionnaire move in the direction of “less depression”, and the changes are almost always largest among Inviters with the Low-SES Guest List (Table D.2).

Literature across the social sciences hypothesizes that interactions with similar-type people are more effective at providing emotional and psychological support (Jacobson, 1987; Lomnitz, 1988; Steffens et al., 2019; Umberson and Montez, 2010). My experimental results, which show that exogenous interactions within-SES lead to larger improvements in psychological well-being than exogenous cross-SES interactions, are consistent with this hypothesis. Evaluating the treatment effects on depression heterogeneously by baseline income *within* low-SES women, I find further evidence that proximity in social-class is a key feature of these relationships that leads to mental health improvements.

I evaluate effects heterogeneously by the SES index, considering women in the first two quintiles as “poorest of the poor” and women in the third and fourth quintiles as “richest of the poor” (recall that women in the fifth quintile are “high-SES”). Among Inviters with the Low-SES Guest List, the poorest and richest of the poor both experience large reductions in depression (Table 7). Among Inviters with the High-SES Guest List, who only have the choice to interact with women in the top quintile of the SES index, the richest of the poor experience depression reductions that are equal in magnitude to the reductions among Inviters with the Low-SES Guest List, while the poorest of the poor experience *no* depression reduction. The benefit of relationships for psychological well-being is *symmetrically* increasing in social-class proximity, implying that low-SES women do not offer some specific resource that is useful for mental health. Rather, the evidence suggests that socially proximate relationships are in themselves a mental health resource.

Consistent with this hypothesis, I find modest evidence that socially proximate relationships improve participants’ subjective experience of social inclusion. Using my primary pre-specified measure of loneliness (the UCLA-3 score), magnitudes follow the same directions across groups as the CESDR-10 score but with much less variation that is not statistically distinguishable across groups (Appendix Table D.23). However, Inviters with the Low-SES Guest List are significantly less likely to say they experienced loneliness ever

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. Depression is measured using the CESDR-10, a 10-item revised version of the Center of Epidemiologic Studies Depression Scale. For each question, participants self-report the frequency with which they experienced the feelings that the question describes in the past two weeks. Each question is answered on a scale of 1-4: (1) Never, (2) Rarely, (3) Sometimes, (4) Always. The CESDR-10 score is the aggregate of these scores across all ten questions. is a score ≥ 10 . The regressions in columns (1)-(2) limit the sample to women in the first and second quintiles of the baseline SES index. The regressions in columns (3)-(4) limit the sample to women in the third and fourth quintiles of the baseline SES index. Low-SES women are in the first four quintiles of the SES index, and High-SES women are all in the top quintile of the SES index.

or often in the past two weeks when I pose the question directly.³⁸

Why do relationships with people who are proximate in the distribution of socio-economic status serve as a mental health resource? Inviters with the Low-SES Guest List are far more likely than Control or Inviters with the High-SES Guest List to share secrets with their own friends rather than with relatives (Appendix D.18). While I do not collect the data to explain why sharing secrets with a friend might improve mental health relative to sharing secrets with extended family members, it is conceivable that women’s own friends are able to provide more empathy for sensitive issues, and that talking to a non-relative can widen the range of sensitive topics they can discuss.

5.3 Discussion of Results

In this section, I present descriptive and exploratory evidence to address several questions that follow from the results.

5.3.1 What social frictions does the Inviter treatment resolve?

I argue that the Inviter treatment reduces the costs of initiating social relationships, and resolves information asymmetries about others’ willingness to interact. What specific costs and information asymmetries do women face in social interactions?

Evidence of High Face-to-Face Social Costs of Initiating Relationships

At baseline, I implement vignettes to understand social norms around meal-sharing and the barriers that women face when sharing meals with other women in the village. Respondents describe how the fact that people share food both for companionship and to assist the needy leads to deep concerns about burdening others, stigmatizing others, or stigmatizing oneself. Seventy-five percent of respondents say that the primary issues likely to hold someone back from visiting a neighbor for a meal are monetary concerns.³⁹ As hosts, respondent report a mix of financial concerns and purely social concerns. Twenty-six percent of respondents believe that financial constraints would inhibit someone from inviting a neighbor for a shared meal, such as not having enough food to share with the neighbor, while twenty-eight percent cite emotional and social barriers, such as worry that the neighbor does not like her.

Seventy-five percent of respondents report that these hypothetical women’s concerns are

³⁸Measures of subjective experience of social inclusion are likely context-specific, and are either minimally validated or not validated at all in settings such as rural Malawi. Following Banerjee et al. (2023), which constructs a plain-language question to measure loneliness to address context and validation issues, I convert a question from the CESDR-10 scale – “How often in the past two weeks did you experience loneliness?” – into two binary measures of loneliness depending on the frequency of loneliness experience.

³⁹For example: fear of burdening the neighbor financially, fear of appearing poor, and fear of not having the monetary resources to reciprocate a shared meal.

Figure 3: Belief Updating

justified. The high cost of face-to-face interaction is validated by revealed preference through the experiment. Only 34% of Inviters, less than half of the women who send any invitation, accompany the enumerator to deliver the invitations to Guests.

Evidence of Information Asymmetries

I ask women at baseline: What percent of women similar to you in the village do you believe would accept an invitation for a shared meal from you? On average, participants believe that 50% of women similar to her in the village would accept her invitation (Figure A.6). One year after the experiment, participants report that 63% of invitations resulted in a shared meal, an invitation acceptance rate that is 26% higher than the mean, and outside the interquartile range, of the baseline believed acceptance rate. This evidence indicates that there is a significant information asymmetry whereby women systematically and pluralistically underestimate others' willingness to share meals.

At midline, participants positively update their beliefs about others' willingness to interact, which is the time when they observe high rates of meal-sharing in the community (Figure 3, left-side panel). By endline, the distribution of beliefs is no longer distinguishable from the baseline distribution, suggesting that correcting beliefs about aggregate willingness to interact is not a sufficient intervention (Figure 3, right-side panel). Without knowing who specifically is willing to interact, or without a third party bearing the face-to-face costs of the initial interaction, meal-sharing activity slows and beliefs revert to their initial distribution.⁴⁰

No Evidence for Lack of Mutual Consent and Reciprocation

Conditional on sending an invitation, meal-sharing is very high and is not different by

⁴⁰Among Inviters but not among Control, midline meal-sharing behavior changes conditionally on baseline beliefs, even though Control participants also update their beliefs positively about others' willingness to share meals, validating that behavior is constrained by more than biased beliefs. Inviters with the *most* pessimistic baseline beliefs share more meals in the past week than Control (Figure A.7). The gap closes among participants who thought at baseline that 45% of women in the village would accept her invitation—the women whose beliefs should *not* update at midline, since 45% of Inviters shared at least one meal with Guests within one month.

Guest-SES. Sixty-four percent of Guests who receive an invitation report that their reaction to receiving the invitation is unambiguously positive, such as feelings of happiness or excitement, while only 4% report any unambiguously negative feelings, such as discomfort or feeling obligated.⁴¹ Furthermore, among Guests with whom Inviters actually share a meal, almost all reciprocate and host a shared meal in return (Figure C.2).

While I cannot rule out that the rate of accepting exogenous invitations would be lower outside the experiment, the reported rejection rate to invitations sent outside the experiment is similar to the within-experiment rejection rate.⁴² Furthermore, Control participants who have an invitation rejected outside the experiment are balanced on observable characteristics with Inviters whose invitations are rejected within the experiment (Appendix Table B.8).

No Evidence that Low-SES Women Under-estimate Returns to Relationships

In response to hypothetical vignettes, almost all respondents report that a high-income neighbor would be helpful for finding income, and that a low-income neighbor would be helpful for reducing loneliness (Appendix Figure C.3). While the majority of respondents also believe that a low-income woman would be helpful for earning income, and a high-income neighbor would be helpful for reducing loneliness, responses are less optimistic, demonstrating that women understand the specific benefits that high-SES and low-SES relationships offer.

No Evidence that Social Norms Mitigate Negative Externalities

While I cannot comment on men or non-migrant women, who are outside my sample, neither Guests nor Control participants who are proximate to treated participants experience negative spillover effects across the main outcomes (Appendix Table D.28). It is therefore unlikely that social norms leading to low rates of social interaction serve an efficient purpose, such as maintaining an optimal allocation of friendships collectively.

5.3.2 Does the price of meat contribute to homophily in durable networks?

In Section 4, I find evidence that the price of meat constrains low-SES women from engaging in social interaction with high-SES women. To what extent can the price of one shared meal explain income-based homophily in durable social networks?

First, I evaluate the probability that Inviters obtain and save the phone number of the women on the Guest List. Patterns are consistent with first-stage results: Inviters with the High-SES Guest List obtain the phone numbers of their high-SES Guests at the same rate that Inviters with the Low-SES Guest List obtain the phone numbers of their

⁴¹The remaining Guests report nervousness, surprise, no reaction, or that they don't remember.

⁴²Thirty percent of respondents who say they sent invitations outside the experiment had at least one invitation rejected. In the experiment, 21% of people who send invitations don't share meals.

low-SES Guests, with or without the Voucher. Inviters with the Random Guest List, on the other hand, are more likely to obtain the phone numbers of low-SES Guests than high-SES Guests unless they have the Voucher.⁴³

By endline, all arms of the Inviter treatment increase the probability that at least half of the respondent’s network links have an iron-sheets roof by 6.2 percentage points (25%, $p < 0.05$) (Table D.29).⁴⁴ For Inviters with the Random Guest List and the Voucher, the treatment induces more economic diversity in network churn while, for every other group, the intervention induces network churn within the same income groups who enter and exit the network absent the treatment.⁴⁵ Notably, the importance of changes to the diversity of the network churn is minute relative to changes in the total volume of network churn that the treatment induces, implying that the first-and-foremost impact of the Inviter treatment on networks in the long run is to spur any amount of movement in and out of the network.

5.3.3 Does Guest SES or a correlated variable drive heterogeneous results?

SES is correlated with other characteristics, so it is possible that average differences in a characteristic *other* than resources or social status generate heterogeneous treatment effects. Aside from SES, age and network degree are the variables that differ systematically between the invited Guests from the High-SES and Low-SES Guest Lists (Appendix Table C.5). Inviter treatment effects do not consistently depend on Guest age or the number of friends that women on the Guest List have, suggesting that it is SES itself that drives the treatment effects (Appendix Tables D.30, D.31, and D.32).⁴⁶

5.3.4 Are there repercussions to weakening extended family networks?

Inviters are less likely to interact with their husbands’ extended family in secret-sharing, advice-seeking, and lending, and instead engage with their own friends. I do not find any evidence of negative repercussions. In fact, it is the women with the least baseline household decision-making power, who are ostensibly the most vulnerable to family backlash, who experience the greatest depressive symptom reductions—a 59% decrease across all Inviter groups (Appendix Table D.24). These women also experience high rates of network churn among their husband’s family members, suggesting that the intervention

⁴³In Appendix Section ??, I discuss these results through the framework of a ‘meeting bias’ versus ‘friending bias’ accounting exercise. My results suggest that descriptive measures of friending bias may conflate underlying preferences with price-constrained selection into meeting opportunities.

⁴⁴The percent of the network that is high-SES increases among Inviters with the High-SES Guest List by 2.6 percentage points relative to Control (6.5%, $p < 0.10$), but the effect is not detectably different from Inviters with the Low-SES Guest List.

⁴⁵See Appendix Section C.1 for detailed results on economic-diversity-weighted network churn.

⁴⁶Among Inviters with the Random Guest List, a younger Guest List leads to greater depressive symptom reductions (Appendix Table D.33). However, the effects go in the opposite direction for Inviters with the Low-SES Guest List, implying that age cannot drive the heterogeneous results by Guest SES.

enables disempowered women to find new people within the family network to interact with (Appendix Table D.25). Inviters who are ever pregnant during the trial, another group who is vulnerable and likely depends on the extended family, also experience much more network churn in husband’s relatives (Appendix Table D.27). There is also no evidence of deterioration in marriages. If anything, marriages appear to improve, especially among Inviters with the Low-SES Guest List, who are the most likely to discuss marriage and romance with their Guests (Table C.8).⁴⁷

5.3.5 Are the results externally valid?

External Validity of Network Formation Frictions

I conduct a survey of sixty-eight people in Central Malawi that does not restrict the sample on the basis of gender or migrant status. Participants’ beliefs about others’ willingness to accept an invitation are even more pessimistic than in the experimental sample, and male and female beliefs are not different. The majority of both male and female respondents say they would prefer to share more meals per week than they currently do. While it is impossible to say if the experiment would be effective among men or non-migrants, the survey evidence suggests that pessimism and fear of rejection may lead to inaction in a broader sample.

External Validity of Downstream Treatment Effects

External Validity to Other Contexts

While the specific channels through which higher-income peers offer economic advantages to their lower-income friends likely differs across settings, my results offer external validity to a large literature based in high-income countries showing the economic value of information, access, or resources that higher-income and higher-achieving peers offer. My results on mental health symptoms are consistent with a wealth of descriptive evidence identifying a powerful correlational relationship between social relationships and psychological well-being across countries, age groups, gender, and income status. Collins et al. (2022) finds that “relational diversity” in social relationships—that is, more variety and evenness in the types of relationships that people engage in—is predictive of well-being across eight countries, which is consistent with my respondents’ revealed preference for economic diversity in their networks.

⁴⁷Inviters with the Low-SES Guest List are 3.8 percentage points less likely than Control to divorce during the trial (42%, $p < 0.05$, not statistically different from Inviters with the High-SES Guest List) (Appendix Table D.26). Divorce is a feasible route for women in this setting (9% of Control divorce during the study). There are no differences in the strength of relationships or comfort risk-sharing with husbands (Appendix Table D.26), suggesting that the treatment likely does not induce low-agency women to stay in harmful marriages. Ninety-six percent of participants say that there is somebody who they can talk to in case of a quarrel with their husband, and there is no treatment effect on this outcome.

External Validity to Stable Networks

Because my sample is selected on the basis of having recently moved, women’s social networks are likely in disequilibrium. If networks adjust with time, the experiment speeds up the process of social integration. Alternatively, if disadvantage on the basis of income, migrant status, and gender mean these women are perpetually excluded, the treatment is a shock to all women in the sample, including those whose networks are in equilibrium.

I test for treatment effect heterogeneity by log-years in the village. Treatment effects on network churn are driven by new arrivals among Inviters with the Low-SES and Random Guest Lists, while there is no difference in network churn by time in the village for Inviters with the High-SES Guest List (Appendix Table D.34). This suggests that the intervention speeds up network formation between low-SES women that would happen eventually, but creates links across-SES that would never happen over time. Treatment effects on depressive symptoms are not heterogeneous, suggesting that the intervention still stimulates a new *type* of interaction that is positive for mental health and would never happen absent the intervention (Appendix Table D.34).⁴⁸

Consistent with the hypothesis that the high-SES links would not form otherwise, treatment effects on food security and self-employment are not differentiable by time in the village (Appendix Table D.34). Surprisingly, Inviters with the High-SES Guest List who are new arrivals report 144 USD greater farm yields ($p < 0.05$), equivalent to the additional farm yields associated with five years in the village among the Control group.⁴⁹ The effects on farm yields among new arrivals is driven by legume yields, which are positively but noisily associated with time in the village among Control (Appendix Table D.34). Cash crop production, which depends significantly on SES but not on time in the village, increases among Inviters with the High-SES Guest List regardless of years in the village.

6 Conceptual Model of Social Network Formation

What set of preferences and constraints that women face can explain the patterns that I observe in the experiment? I present a conceptual model of social network formation that serves as a lens with which to interpret the experimental results. A key feature of the model is, first, to consider relationships with different types of people as different goods with different benefits, implying that the trade-off across types is a central tension in network formation and that there can be benefits to network diversity. Second, I al-

⁴⁸Treatment effects on mediating variables, such as sharing secrets and having strong-tie relationships with women’s own friends, also are not heterogeneous by time in the village.

⁴⁹This is also roughly the amount of time in the village before the treatment effect fades. Every log-year in the village is associated with a 78 USD lower treatment effect.

low the benefits of relationships to increase in financial investment. When the returns to relationships with higher- and lower-SES people are differentially sensitive to financial investment, the model generates predictions for how the price of high-value social activities can act as a determinant of income-based homophily.

I consider two ways in which individuals obtain utility from social capital, paralleling the Grossman (1972) theoretical formulation of health capital. First, individuals get utility from social interaction itself—the non-market value of being in the company of others—which I refer to as “intrinsic utility”. Secondly, there is a financial return to social interactions, which allows people to consume other utility-generating goods. I refer to the utility of the consumption that individuals can afford because of the financial return on social interaction as the “instrumental utility” of social relationships.

6.1 Model Set-up

Low-SES women decide if they want to initiate relationships with low-SES or high-SES women, and then choose if they will invest financially in these social engagements. First, they select across a set of relationship-initiation bundles (S_L, S_H) , choosing to initiate relationships with low-SES women, high-SES women, none, or both, where they can initiate a maximum of two relationships.⁵⁰ Initiating relationships with low-SES and high-SES women bear fixed effort costs c_L and c_H , respectively. Conditional on initiating at least one relationship, agents choose $I \in [0, 1]$, a continuous level of financial investment to improve the social experience, which costs p^I per unit. Agents spend their remaining income on consumption Z .

Women select S_L , S_H , and I to maximize:

$$\begin{aligned} \max_{S_L, S_H, I} U(Z, V(S_L, S_H, I)) \quad \text{s.t.} \quad & Y(S_L, S_H, I) = Z + p^I \cdot I \cdot (S_L + S_H) \\ & Y(S_L, S_H, I) = \bar{y} + \mathbb{Y}(S_L, S_H, I) \\ & V(S_L, S_H, I) = \bar{v} + \mathbb{V}(S_L, S_H, I) - S_H \cdot c_H - S_L \cdot c_L \\ & I > 0 \quad \Rightarrow \quad S_L + S_H > 0 \end{aligned}$$

where $\mathbb{Y}(S_L, S_H, I)$ is the financial return function for these social interactions, and $\mathbb{V}(S_L, S_H, I)$ is the intrinsic utility return function; $\bar{y}$ is the existing income, and $\bar{v}$ is the intrinsic utility the agent gets from her pre-existing network. All functions are increasing in S_L and S_H , and are continuous and weakly increasing in I . U is concave and additively separable in Z and V .

Assumption 6.1 (Each type has an absolute advantage in producing one type of utility).

⁵⁰i.e., $(S_L, S_H) \in \{(0, 0); (1, 0); (0, 1); (2, 0); (0, 2); (1, 1)\}$.

Without loss of generality, denote types H and L with θ and θ' . Let θ be the type that is more productive in generating a financial return, and let θ' be the type that is more productive in generating intrinsic utility.⁵¹

Assumption 6.2 (One type is more responsive to investment). *Without loss of generality, returns to interaction with the θ -type benefit relatively more from investment than the θ' -type, at all feasible bundles.*⁵²

Let λ_Y be the local marginal utility of income, and let λ_V be the local marginal utility of intrinsic utility, holding S_H, S_L, I , and Z fixed (i.e., local weights on instrumental versus intrinsic utility in the total utility function).

Lemma 6.1 (Existence of a preference space where diversity is optimal). *By Assumption 6.1, there exists a preference space, denoted P (defined formally in Lemma F.1 in Appendix F.2) such that when $\lambda_Y/\lambda_V \in P$ the choice set $(S_L, S_H) = (1, 1)$ generates more utility than the choice sets $(S_L, S_H) \in \{(2, 0), (0, 2)\}$.*

6.1.1 Investment Price Subsidy

Let τ be a subsidy to the price of I , so that $p(\tau) = p^I - \tau$. $S_H^*(0)$ and $S_L^*(0)$ denote the optimal number of high- and low-SES initiations that the agent chooses without the subsidy, and $S_H^*(\tau)$ and $S_L^*(\tau)$ denote the optimal number of initiations under subsidy τ .

Lemma 6.2 (Subsidies induce diversification.). *Assume that $\lambda_Y/\lambda_V \in P$ for all I , and that the difference between c_θ and $c_{\theta'}$ is bound (bounds are defined in Lemma F.2 in Appendix Section F.2). Then, if $S_\theta^*(0) + S_{\theta'}^*(0) < 2$, there exists a subsidy large enough to induce an increase in the number of initiations; and, given the assumed preferences, this subsidy will induce more diversity in the set of initiations.*

6.1.2 Preference Heterogeneity

I introduce two groups of agents $g \in \{g_1, g_2\}$, each with a set of weights $(\lambda_Y^g, \lambda_V^g)$, implying a different set of preferences over financial return and intrinsic utility. Let the first group have the zero-subsidy optimum $(S_\theta^*(0), S_{\theta'}^*(0)) = (0, 1)$ and let the second group have the zero-subsidy optimum $(S_\theta^*(0), S_{\theta'}^*(0)) = (1, 0)$ with $I_{g_1}^*(0) = I_{g_2}^*(0) \in [0, 1]$. All other model primitives remain constant across the two groups. I assume that the complementarity between interactions with θ and θ' -types is bound so that the difference in weights across groups g_1 and g_2 can never be large enough to overturn the advantages of each type as described in Assumption 6.1.⁵³

⁵¹Mathematical statement is Assumption F.1 in Appendix Section F.2.

⁵²Mathematical statement is Assumption F.2 in Appendix Section F.2.

⁵³The mathematical statement is Assumption F.3 in Appendix F.2.

I define $\tau_{g_1}^+$ as the minimal subsidy that induces a θ -type initiation among g_1 group members, who prefer θ' -types without the subsidy; and $\tau_{g_2}^+$ as the minimal subsidy that induces a θ' -type initiation among g_2 group members, who prefer θ -types without the subsidy. Note that $\tau_{g_1}^+$ and $\tau_{g_2}^+$ are the minimal subsidy described in Lemma 6.2, conditional on different sets of preferences.

6.2 Comparative Statics

Proposition 6.1 (Diversification conditional on zero-subsidy preferences). *Let Assumptions 6.1 and 6.2 hold and assume that $\lambda_Y^g/\lambda_V^g \in P$, $\forall I \in [0, 1]$, $g \in \{g_1, g_2\}$.*

(a) **(Substitution Across Types)** *Fix effort costs $c^0 = (c_\theta^0, c_{\theta'}^0)$, where $(c_\theta^0 - c_{\theta'}^0)$ is bound so that Lemma (6.2) holds for each group $g \in \{g_1, g_2\}$. Let $\tau_{g_1}^+(c^0)$, $\tau_{g_2}^+(c^0)$ be the minimal subsidies required to induce more initiations, given effort costs c^0 . Then $\tau_{g_1}^+(c^0) < \tau_{g_2}^+(c^0)$ and, whenever the subsidy $\tau \in (\tau_{g_1}^+(c^0), \tau_{g_2}^+(c^0))$:*

- *Individuals will diversify in response to the subsidy iff they prefer θ' (the type less responsive to financial investment) in the zero-subsidy counterfactual*
- *Across all agents, the number of θ -type initiations increases*
- *Across all agents, there is no change to the number of θ' -type initiations*

(b) **(One Type is Infeasible)** *Define $\bar{c}_\theta$ as the minimal effort cost such that it is never worth it to initiate a relationships with a θ -type. Define $\bar{c}_{\theta'}$ analogously.⁵⁴ Each agent k experiences a shock to the effort cost of initiating a relationship with one type (the effort cost to initiate with the other type remains fixed), so that effort costs are $(c_\theta^k, c_{\theta'}^k) \in \{(c_\theta^1, c_{\theta'}^0), (c_\theta^0, c_{\theta'}^1)\}$, with $c_\theta^1 > \bar{c}_\theta$ and $c_{\theta'}^1 > \bar{c}_{\theta'}$ (the type of shock that the agent experiences may vary within and across (g_1, g_2)).*

Choose a subsidy $\tau^ \in (\tau_{g_1}^+(c^0), \tau_{g_2}^+(c^0))$.⁵⁵ Then, even if the shares of agents experiencing the two effort cost shocks are equivalent, and even if $S_\theta^*(0) = S_{\theta'}^*(0)$ and $I_{g_1}^*(0) = I_{g_2}^*(0)$:*

- *Across all agents, it is possible that the subsidy induces no difference in the relative aggregate change in initiations with the θ -types and θ' -types.*

All model proofs are in Appendix Section F.2.

By assumption, a sufficiently large subsidy induces diversity in initiations. Proposition 6.1(a) shows that a fixed subsidy is more likely to induce diversification among people

⁵⁴The mathematical definition is Appendix F.2 Equation 12.

⁵⁵I calculate the subsidy using behavior with effort costs c_0 ; I evaluate behavior under effort costs $(c_\theta^k, c_{\theta'}^k)$.

who, without a subsidy, prefer to initiate relationships with the type that is less responsive to investment. The experiment enables me to measure if participants perceive the returns to social interaction with high- or low-SES women to be more sensitive to financial investment, and the model generates implications about what this means for network formation patterns. In the model, the returns to interacting with θ -type women are more sensitive to financial investment. Then, if:

1. $\theta = H$ and $\theta' = L$: high prices of social interaction constrain cross-SES linking and contribute to income-based homophily
2. $\theta = L$ and $\theta' = H$: high prices of social interaction constrain within-SES linking and enable more economic connectedness
3. Neither type are sensitive to financial investment: high prices of social interaction do not contribute to the economic composition of networks

Proposition 6.1(b) highlights an important counterfactual: even if marginal returns to investment are higher with one type, a subsidy may fail to shift behavior when the margin of substitution is shut down because *all* relationships may be beneficial even without investment. Evaluating this counterfactual can reveal if prices are a *feasibility* constraint, or if, as the model proposes, the relative returns to initiating relationships with high-SES and low-SES links changes across the price domain, driving differences in network composition across prices.

6.2.1 Mapping Results to the Model

The invitation response patterns show that high- and low-SES relationships are distinct goods, where each type provides unique benefits that are both valuable, implying that economic diversity in social interactions is most-preferred (Assumption 6.1).⁵⁶ The Voucher makes multiple interactions with a diverse set of people even more attractive. Because this shift comes from an increase towards high-SES links, I interpret the perceived benefits of high-SES relationships as more sensitive to financial investment. The model tests also clarify the nature of constraints that inhibit cross-SES linking. High-SES invitations increase in response to the voucher only when Inviters can choose between high- and low-SES Guests, but not when they are restricted to high-SES Guests alone, indicating that high-SES relationships are not infeasible at high prices. Instead, they are relatively less attractive than low-SES alternatives due to their greater sensitivity to investment.

⁵⁶Appendix Section F.1 details the relationship between the model predictions and empirical tests, and Appendix Table F.1 presents the first-stage results as a set of empirical tests of the model predictions.

7 Conclusion

My results add to our understanding of social network formation in three important ways. First, I show, while social capital is broadly beneficial, the types of benefits that it provides vary by the nature of the tie. In my setting, within-SES links yield large mental health benefits, while cross-SES links yield large benefits for food security. If people value both food security and mental health, this implies that people also value economic *diversity* in their networks.

Second, I find that information frictions and effort costs of the activities that form or strengthen network links are prohibitive. Resolving these frictions is remarkably easy, and leads to large positive treatment effects for *both* cross-SES and within-SES links, without any evidence of displacing the returns to social relationships from anyone else in the sample. These results suggest that there is likely a significant market failure in the creation of new social relationships.

Third, I show that the price of valuable social interaction serves as an important barrier to social connection, and that, without intervening on price specifically, links may form or strengthen in ways that can even reinforce existing inequities. This insight into social network formation has important implications for development policy. While evidence shows that group-based development programs—a common tool to execute development policy—have important exogenous economic impacts ([Annan et al., 2013](#); [Beaman et al., 2014](#); [Karlan et al., 2017](#); [Ksoll et al., 2016](#)), these are often reported as average impacts and may be concentrated among the relatively higher-income households in a village. Indeed, there is evidence suggesting that development policy relying on self-selection and group-based selection does not reach the poorest households ([Lønborg and Rasmussen, 2014](#)). My results show that this exclusion may be at least in part driven by social capital deficits, which is not a determinant that need be strictly relevant for the efficacy of the intervention. Without measuring the distributional impacts of group-based interventions and without being deliberately inclusive, development programs may ignore or deepen social and economic vulnerability of the most marginalized populations. A promising avenue for future research is to test, when introducing interventions in which women form groups themselves, if providing lower-income women with the opportunities and financial means to engage in valuable social activities can help them to be included.

Furthermore, a review of group-based interventions among women found that the primary mechanism through which group-based interventions are successful is their ability to reach many women at once, rather than the social interactions that they foster ([Díaz-Martin et al., 2023](#)). My experiment, which generates large positive treatment effects by helping loose acquaintances spend time together in a meaningful way, suggests that the absence of social interaction effects in many group-based interventions may not be

surprising since these interventions often do little more socially than bring people to the same place. Without understanding and removing specific barriers to *meaningful* social interaction, group-based interventions may be ineffective at generating social connection, especially for people who are systematically left out. At the same time, including the most marginalized groups can induce a virtuous cycle: social connection alone generates large positive treatment effects on economic and psychological well-being, which, when paired with other development initiatives, has theoretical grounds to significantly improve their efficiency. *Inclusive* development policy may require specific efforts to help marginalized community members build and access social capital.

Table A.3: Closeness of a Conversation Across Settings

	(1) Full Sample	(2) Thinking About a Meal-Sharing Friend	(3) Thinking About a Work Friend	(4) Female Sample	(5) Male Sample
Conversation Over a Meal	1.282*** (0.150)	1.276*** (0.212)	1.303*** (0.161)	1.249*** (0.159)	1.452** (0.443)
Friend from Work	0.020 (0.119)			0.023 (0.134)	-0.000 (0.256)
Observations	504	252	252	432	72
Mean in Other Settings	2.045	2.042	2.048	2.123	1.574

Standard errors in parentheses

The outcome is how personal a conversation could become in a given setting, and with a given person, on a scale from 1 to 5 (where higher numbers indicate more personal conversations). Each survey participant was asked to consider a conversation across four settings: over a meal, while working, while doing chores, or while at work. They were also asked to consider two types of people: a person with whom they often share meals, and a person with whom they often work together. The order of questions was randomized. Each observation is at the question level (with eight observations per participant). All regressions include individual fixed effects and fixed effects for the order in which they were asked the question. Standard errors are clustered at the individual level.

* $p < 0.10$, ** $p < 0.05$, *** $p < .01$

Figure A.5: Preferred versus Actual Meal-Sharing

Figure A.6: Pluralistic Ignorance

Figure A.7: Baseline Beliefs and Midline Meal-Sharing

Figure A.8: Asset-Based Village-Level Homophily

A.1 Business Capital Index Construction

I create a proxy for business capital in the following way: each enumerator estimates the fixed costs of establishing each business type. I regress the within-enumerator rank of fixed costs on an indicator for the business type, and use the coefficient as a measure of business capital, controlling for the enumerators’ stated confidence in their response. Enumerators come from within these communities, and several have family members or friends engaged in these types of businesses. Furthermore, they have a fairly high degree of agreement about the relative rankings of different business types.

A.2 Cluster-level Program Saturation

I randomize the saturation of the Inviters and Guests at a geographic cluster level. In a “high-saturation” cluster, 87% of eligible women are randomized to be Inviters or Guests, and 13% of women are randomized to Control. In a “low-saturation” cluster, 35% of eligible women are randomized to be Inviters or Guests, and 65% of women are randomized to Control. First, I define geographic clusters. Then, I randomize each cluster to high or low saturation. Finally, I randomize individuals within clusters to treatment assignments, using the ratios as defined by their cluster-saturation-type.

I define geographic clusters using k-means clustering following [Poll \(2024\)](#). This unsupervised learning technique creates groups based on similarities in latitude and longitude. I specify that clusters must have at least 20 people in them, and should have 36 people per cluster on average. I choose 36 as the average size so that I attain around 100 clusters, in order to ensure sufficient statistical power to detect differences across Control respondents in high- and low-saturation areas. In order to ensure that this is a relevant geographic unit for social networks, I link the names of social network connections with people in my listing dataset and calculate how many relationships with someone in my sample are within the same cluster. I am able to link 7% of network links. Seventy percent of these links are within the same cluster, indicating that this is a network-relevant geographic unit. It is important to note that the relationships between respondents in my sample (the names who I can link) are not representative relationships. They are on average 4.4 minutes (58%) walking-distance closer than other relationships, and are 5 percentage points (16%) less likely to be relatives. However, these relationships are likely good approximations for the types of relationships that my intervention creates.

A.3 Sharing List Construction Details

There are 68 participants (52 Inviters) who are randomized into the Intervention Sample but who attrit from the Treatment Allocation Survey. These participants are randomly replaced with women who originally are randomized to Control and who live in the same

geographic cluster as the attriter. In all but 19 cases, I also am able to randomly select a woman from the same wealth quintile, to hold strata constant. In the cases where there is not a Control household available from the same geographic cluster and the same wealth quintile, I select a woman from the same geographic cluster and the proceeding or succeeding wealth quintile. Because the names from the Sharing List that each Inviter sees is dependent on *other* Inviters' Sharing Lists, I do not reconstruct the Sharing List for these replacement households, meaning that, for replacement households, the Guests available for them to invite are not necessarily within 800 meters.

A.4 Variables Construction Details

Food Security Index

For each index, I take the first component of the PCA of the variables entering the index. Each index is then normalized into standard deviation units from the Control mean.

Midline Food Security Index Variables:

1. How many days in the past month did you eat fish? + How many days in the past month did you eat eggs?
2. On a typical day in the past month, how many meals did you eat?

Endline Food Security Index Variables:

1. How many days in the past month did you eat fish? + How many days in the past month did you eat eggs? + How many days in the past month did you eat meat?
2. On a typical day in the past month, how many meals did you eat?
3. How many days during the most challenging period this past growing season did you eat fish? + How many days during the most challenging period this past growing season did you eat eggs? + How many days during the most challenging period this past growing season did you eat meat?
4. On a typical day during the most challenging period this past growing season, how many meals did you eat?

I define the lean season as the time during the past growing season where participants report facing the most financial hardship. On average, households report that this time period lasted eleven weeks. In the Control group, 64% report that they ate one meal per day during this time period, and only 6% report that they ate three meals per day. The endline survey is conducted right after the harvest, so food security measured over the past month represents the theoretical best time for food security. Consistent with extreme swings in consumption following the agricultural seasons, in the Control group,

only 5% report typically eating one meal per day in the past month, while 36% report eating three meals per day.

Strength of Ties

These five variables entering the strength of ties measure are the following:

1. How comfortable would you feel to trust [NAME] with your thoughts and feelings? (*Five-point Likert scale*).
2. How easy is it for you to laugh with [NAME] when you are together? (*Five-point Likert scale*).
3. “Who do you share secrets with?” (*Binary, =1 if selects name of given tie*).
4. Inclusion-of-Self in Others Score (*Visual measure of relationship “closeness” on a 7 point scale*).
5. Confidante reciprocity status (*0 if the tie is not a confidante; 1 if the tie is a confidante, but the relationship is certainly not reciprocated; 2 if the tie is a confidante, and the relationship is probably not reciprocated; 3 if the tie is a confidante and the relationship is most likely reciprocated; 4 if the tie is a confidante and the relationship is certainly reciprocated*).

Crop Classes

I classify crops into five crop classes: maize, other starches, fruits and vegetables, legumes, and cash crops.

Other starches include: cassava, sorghum, rice, Irish potatoes, and sweet potatoes.

Fruits and vegetables include: bananas, leafy greens, tomatoes, onions and pumpkins.

Legumes include: soy beans, plain beans, groundnuts, pigeon peas, and cowpeas.

Cash crops include: sugar cane, tobacco, and sunflower seeds.

A.5 Text Analysis

In the endline survey, enumerators ask Inviters about their experience with each Guest who they sent an invitation to; and ask Guests about their experience with each Inviter who they received an invitation from. Enumerators also ask all respondents about their overall opinions of the program. I conduct a text analysis from these text responses. Across all of the possible text response variables, I compute the cosine similarity of the text response to a set of key-words. I code each row as falling within a category if the cosine similarity is ≥ 0.6 .

If text is similar to multiple key phrases, they are assigned a category based on the following priority ordering: (1) strong relationships, (2) any other relationships, (3) no relationship, (4) other.

The breakdown of text analysis categorizations is the following:

Table A.4: Text Analysis

	Strong Relationship	Any Relationship	No Contact	Other
Inviters	229	308	265	125
Guests	153	251	275	73

Phrases indicating “strengthened relationships”:

”closer now”, ”grew closer”, ”became close”, ”we talk often”, ”grew close”, ”closer together”, ”we are close now”, ”stronger friendship”, ”stronger relationship”, ”closer than before”, ”friendship grew”, ”our bond”, ”bond grew”, ”bond stronger”, ”love”, ”relationship improved”, ”friendship improved”, ”we are still friends”, ”we are good friends”, ”we continue”, ”we keep”, ”we still”, ”persist”, ”more open”, ”united”, ”support each other”, ”encourage each other”, ”help each other”, ”sharing continues”, ”sharing food regularly”, ”continued sharing”, ”always together”, ”keep meeting”, ”continue sharing”, ”we still see each other”, ”we still meet”, ”we visit each other”, ”we visit often”, ”we still visit”, ”we are in touch”, ”we keep in touch”, ”we remain friends”, ”we are friends”, ”we are close”, ”we became closer”, ”our relationship is good”, ”relationship continues”, ”she helps me”, ”he helps me”, ”we help one another”, ”we support one another”, ”she encourages me”, ”he encourages me”, ”we encourage one another”, ”we are still together”, ”always together”, ”still together”, ”friendship continues”, ”friendship persists”, ”we remain close”, ”we became united”, ”we are still united”, ”relationship is strong”, ”friendship is strong”, ”friendship remains”, ”relationship remains”, ”bonds much stronger”, ”encouraging each other”, ”increases our relationship”, ”we are friends”, ”strengthen our relationship”, ”friendship very strong”, ”share meals sometimes”

Phrases indicating “any relationship”:

”became friends”, ”made a friend”, ”started talking”, ”she visits”, ”he visits”, ”now friends”, ”friends now”, ”our bond”, ”we get along”, ”invited to my home”, ”we met and chat”, ”visited me”, ”went to her house”, ”we know each other now”, ”we chat”, ”we chatted”, ”chatting”, ”talked”, ”discussed”, ”greeted each other”, ”we still chat”, ”conversation”, ”just chatted”, ”just chatting”, ”chat here and there”, ”i forgot what we discussed”, ”share food”, ”share meals”, ”first time we met”, ”she came for the first time”, ”she introduced herself”, ”he introduced himself”, ”introduced me”, ”we started as friends”, ”began visiting”, ”share things”, ”shared with me”, ”sharing my meal”, ”we

talked about", "we ate together", "discussing about", "we do share meals", "it has made them to know each other", "we talked more", "we really talked"

Phrases indicating "nothing happened":

"nothing happened", "nothing", "didn't happen", "did not happen", "she never came", "he never came", "we didn't meet", "we did not meet", "didn't share", "did not share", "never visited", "no friendship", "didn't invite", "not invited", "never invited", "did not receive invitation", "she refused", "he refused", "we haven't met", "never met", "don't know her", "don't know him", "don't know her", "don't know him", "moved away", "she moved", "he moved", "we have never meet", "can't recall being invited", "can't remember being invited", "i wasn't invited", "no invitation", "invited but didn't go", "couldn't make it", "wasn't available", "missed the meeting", "can't recall being invited", "did hear I was invited", "don't remember the person", "name is new", "moved to another village", "moved away", "at a funeral", "did not manage to go", "wasn't invited by her", "never received any invitation", "did not receive invitation", "never discussed anything concerning this program", "never turned up", "never showed up", "didn't show up", "she refused to come", "he refused to come", "she denied", "he denied", "she ignored", "he ignored", "not available", "we never interacted", "we never connected", "did not show up", "we have never eaten", "we did not talk", "meeting was canceled", "never met", "she didnt find her", "did not invite me", "never invites me", "never invited me"

Appendix B Balance and Attrition

B.1 Baseline Balance

Table B.1: Baseline Balance: Comparing Control with Inviters

C.1 Economic Diversity-Weighted Network Churn

My measure of economic diversity-weighted network churn is:

$$Churn^{Diverse} = (Dropped + New) \cdot \left(\frac{(Dropped_{IS} + New_{IS}) \cdot (Dropped_{Th} + New_{Th})}{Dropped + New} \right)^\alpha$$

where *Dropped* is the number of dropped links, *New* is the number of new links, *IS* subscripts ties that have iron-sheets roofs, and *Th* subscripts ties that have thatched roofs, $Dropped = Dropped_{IS} + Dropped_{Th}$ and $New = New_{IS} + New_{Th}$. Finally, α is a parameter that weights the importance of diversity relative to volume. Note that, if $\alpha > 0$, the total measure is maximized when network churn among ties with iron-sheets roofs is equal to network churn among ties with thatched roofs.

I regress $Churn^{Diverse}$ on my treatment indicators across a range of values for α . If the treatment effect is maximized when $\alpha = 0$, then the intervention purely induces a greater volume of network churn, among the same types of ties (by income) that we would expect in the absence of the treatment. Conversely, if $\alpha > 0$, then the intervention induces both a greater volume of network churn and more diversity (by income) in who enters and exits the network. For almost every group, $\alpha^* = 0$ maximizes treatment effects of that group, indicating that the intervention induces a larger volume of network churn within the same groups who would enter and exit the network to a lesser extent in the absence of the treatment. However, consistent with the first-stage treatment effects on invitation-sending, this is not the case among Inviters with the Random Guest List and the Voucher. The α that maximizes the treatment-effect is $\alpha^* = 0.016$, indicating that Inviters with the Random Guest List and the Voucher have a more economically-diverse set of ties enter and exit their networks.

Table C.10: $\alpha^* := \alpha$ that Maximizes Treatment Effects on Diversity-Weighted Network Churn

Inviter Arm	α^*
High-SES Guest List without the Voucher	0
High-SES Guest List and the Voucher	0
Low-SES Guest List without the Voucher	0
Low-SES Guest List and the Voucher	0
Random Guest List without the Voucher	0
Random Guest List and the Voucher	0.016

I construct a measure of network churn that is weighted by economic diversity of individuals entering and existing networks: $(Dropped + New) \cdot (p^{IS} \cdot (1 - p^{IS}))^\alpha$, where p^{IS} is the percent of individuals who enter or exit the network that have an iron sheets roof. I regress this measure on my treatment indicators across a range of α . In this table I report α^* , the α that maximizes the treatment effects for each treatment indicator.

While $\alpha^* > 0$ provides evidence that patterns in invitation-sending carry through to

actual changes in the network, the difference between the magnitude of the treatment effect among Inviters with the Random Guest List and the Voucher when $\alpha = 0.016$ and when $\alpha = 0$ is minute. When $\alpha = 0.016$, the Inviter treatment with the Random Guest List and the Voucher leads to a 0.698-person increase in network churn. When $\alpha = 0$, the same group leads to a 0.696-person increase in network churn.

All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. Depression is measured using the CESDR-10, a 10-item revised version of the Center of Epidemiologic Studies Depression Scale. For each question, participants self-report the frequency with which they experienced the feelings that the question describes in the past two weeks. Each question is answered on a scale of 1-4: (1) Never, (2) Rarely, (3) Sometimes, (4) Always. The CESDR-10 score (column (1)) is the aggregate of these scores across all ten questions. (column (2)) is a score ≥ 10 ; (column (3)) is a score from 10-15; (column (4)) is a score from 16-21; and (column (5)) is a score ≥ 22 .

D.0.1 Other Plausible Mediators for Increased Food Security

There are several mediators for increased food security that are plausible and for which I have suggestive evidence, but do not have the data to make conclusive statements. Thus, the following discussion is well-motivated theoretically, but speculative.

Reduced Household and Farm Expenditures

Inviters change the crops that they cultivate, so Inviters may face different input costs throughout the agricultural season. While I do not collect detailed data on farm expenditures, I do measure fertilizer use and adoption of new agricultural technologies, which both noisily decrease among Inviters (Table D.8 columns (1)-(3)). This set of results suggest that farm inputs may change and, since Inviters do not experience a reduction in total farm yields, that Inviters may use farm inputs more efficiently.

Because Inviters are more likely to join “Welfare Groups”, they may incur fewer household expenditures. The most common groups operate like informal health or life insurance. Households agree in advance to an amount that they will contribute to any member who experiences illness or death of a family member. In some groups, each member contributes at the time of the shock, and in other groups, all the members contribute to a central pot of money on a regular basis which then becomes the pool of money to draw on when a household experiences a shock. Affected members do not incur any debt, and contributing members are not paid in return, but reciprocity is expected in the event that another member faces a shock. In a variation of these groups called ‘Chi Sick’, members agree to serve as one another’s guardians in the hospital in case of illness, insuring against non-financial risks associated with health shocks. In other variants, households pool resources to purchase goods in bulk as a group, thereby benefiting each member with lower per-unit prices. In “Kitchen Top-Up Groups”, women pool resources to purchase kitchenware, which they then share as a group. In “Grocery Top-Up Groups”, women pool resources to purchase groceries in bulk, enabling them to purchase goods at a lower per-unit price.

Reduced Savings

Households may have consumed more by withdrawing from their savings. Maize stores, the measure of savings I collect, is a reliable measure since it is a standard method of holding assets that enumerators visually verify. However, since the Inviter treatment changes the method through which people earn, the method that they save could change as well. Reduced maize stores could simply be a reflection of crop diversification. There is a noisy reduction in maize stores (15 fewer kilograms, 8% of the Control mean), but not statistically significant (Table D.8 columns (4)-(5)).

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. The outcome of columns (1)-(2) is an indicator variable that takes the value of 1 if the respondent reports that she earned income through self-employment in the past month. The outcome of columns (3)-(4) is an indicator variable that takes the value of 1 if there is any household member who earned income in the past month through a self-employment activity that they did not earn income from in any prior survey. The outcome of columns (5)-(6) is an indicator that takes the value of 1 if the household began engaging in the same self-employment activity as one of the women on her sharing list, and she did not report participating in this same activity in a prior survey. To construct this measure for the Control group, we construct a placebo Sharing List, so that the Control mean effectively represents the rate of switching into one neighbor's self-employment activities that we should expect absent the intervention.

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. The outcome for each column indicates if the participant grew at least one crop in the column's given crop category. Other starches include: cassava, sorghum, rice, Irish potatoes, and sweet potatoes. Legumes include: soy beans, plain beans, groundnuts, pigeon peas, and cowpeas. Fruits and vegetables include: bananas, leafy greens, tomatoes, onions and pumpkins. Cash crops include: sugar cane, tobacco, and sunflower seeds.

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. For each network tie, participants report their comfort in borrowing from or lending to that person on a Likert scale. The outcomes in columns (1) and (2) report the number of those friends for whom that participant said she would be lending to. The outcomes in columns (3) and (4) report the number of those friends for whom the participant said she would be borrowing from. The outcome of columns (5) and (6) indicates membership with a rotating savings and credit association, a semi-formal savings and borrowing group. The outcome of columns (7) and (8) indicates membership with a Village Savings and Loan Association, a semi-formal savings and borrowing group.

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. Network Degree (columns (1)-(2)) is the total number of members in the network. New Network Ties (columns (3)-(4)) is the number of network ties in any given survey who were not listed in the network in the baseline survey. Dropped Network Ties (column (5)-(6)) is the number of network ties who were listed in the baseline survey but who were not listed in the given survey.

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. Network churn among weak ties (columns (1)-(2)) is the number of dropped baseline ties who are defined as weak ties at baseline, plus the number of new ties who are defined as weak ties in the relevant survey round. In other words, it is a measure of changing links within ties of a given strength (whether change is by entry or exit from the network). The analogous definition holds for mid-strength ties (columns (3)-(4)) and strong ties (columns (5)-(6)). Strength-of-ties is evaluated using five variables: the ability to trust the network link with thoughts and feelings (Likert scale), ease of laughing with the network link (Likert scale), if the link is someone with whom the participant shares secrets (binary), degree to which sharing stories in the relationship happens, and to which it is reciprocal (Likert scale), and the Inclusion-of-Self in Others (ISO) scale (1 to 7). I conduct a PCA analysis of these five variables, using the full sample in the Baseline Survey. I then apply the first principal component weights on these five variables to the same variables in all the surveys. This way, I use the levels and correlation structure of these variables from the Baseline Survey to analyze strength of ties in ensuing survey rounds. This also allows me to construct a levels comparison in strength-of-ties over time. Weak ties are defined as ties whose strength-of-ties index is below the 20th-percentile of tie-strength in the Baseline Survey. Strong ties are defined as ties whose strength-of-ties index is equal to the maximum tie-strength in the Baseline Survey. Mid-strength ties are defined as all ties with an intermediate tie-strength.

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. Depression is measured using the CESDR-10, a 10-item revised version of the Center of Epidemiologic Studies Depression Scale. For each question, participants self-report the frequency with which they experienced the feelings that the question describes in the past two weeks. Each question is answered on a scale of 1-4: (1) Never, (2) Rarely, (3) Sometimes, (4) Always. The CESDR-10 score is the aggregate of these scores across all ten questions. Mild-to-severe depression is a score ≥ 10 . The regressions in columns (1)-(2) limit the sample to women who, at baseline, said that only her husband or someone else is the primary decision-maker about childcare (including schooling, health, and discipline), whether and when to have a child, and household savings. The regressions in columns (3)-(4) limit the sample to women who, at baseline, said that they are the primary decision-maker (jointly or alone) for between one and four of these five household decisions. The regressions in columns (5)-(6) limit the sample to women who, at baseline, said that they are the primary decision-maker (jointly or alone) for all five household decisions.

Control Mean	0.752	0.016	0.145	0.090	5.093	0.887
P-values:						
Pooled: High-SES vs. Low-SES Guest List	0.289	0.861	0.470	0.230	0.942	0.497
Pooled: Voucher vs. No Voucher	0.924	0.942	0.256	0.293	0.296	0.761

Standard errors in parentheses. $*p < 0.10$, $**p < 0.05$, $***p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. Still Married (column (1)) takes the value 1 for respondents who were married at baseline and are still married to the same person at endline, and 0 otherwise. Newly Married (column (2)) takes the value 1 for respondents who were single at baseline and are now married, and respondents who were married at baseline and are now married to a new person, and 0 otherwise. Divorced, Separated, or Widowed (column (3)) indicates if a respondent is currently divorced, separated, or widowed, and not remarried. Newly Divorced (column (4)) takes the value of 1 if a respondent was divorced over the course of the past year since baseline – women who said they were married at baseline, who at endline say they are divorced – and 0 otherwise. I ask all participants about their subjective relationships with their husbands and, whether or not they list their husband in the network, I compute strength of ties the same way for husbands that I do for other network members. The outcome for column (5) is the strength of the tie with the husband. The outcome for column (6) takes the value 1 if the respondent says she would be very uncomfortable to both borrow and lend to her husband, and 0 otherwise. There are only 11 people in the sample who have never been married.

Table D.27: Treatment Effects on Husband's Relatives within the Network: by Child-Rearing Intensity

Standard errors in parentheses

All specifications include baseline unbalanced control variables (moved to the village for marriage), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. The Food Security Index (columns 1 and 2) is a PCA index in standard deviations from the Control mean. The Food Security Index at 1 Month is a PCA index of: the typical number of meals consumed per day in the past month, and the number of meals with fish or eggs consumed in the past month. The Food Security Index at 1 Year is a PCA index of: the typical number of meals consumed per day in the past month, and the number of meals with meat, fish or eggs consumed in the past month, the typical number of meals consumed per day during the lean season, and the number of meals with meat, fish or eggs consumed during the lean season. To calculate the Farm Yields in USD value (column 3), households estimate their harvest yields for each crop. I multiply market rates in agricultural reports by yields for the most high-yield crops: maize, soy beans, groundnuts, beans, tobacco, sugar cane, sunflower seeds, sweet potatoes, and pumpkin. Depression is calculated using the CESDR-10, a 10-item revised version of the Center of Epidemiologic Studies Depression Scale. (columns 4 and 5) indicates a score greater than or equal to 10.

Pooled: High-SES vs. Low-SES Guest List	0.014**	0.184	0.815	0.621	0.939	0.267
Pooled: Voucher vs. No Voucher	0.926	0.839	0.483	0.911	0.579	0.032**
High-SES: Voucher vs. No Voucher	0.684	0.633	0.848	0.997	0.569	0.375
Low-SES: Voucher vs. No Voucher	0.550	0.941	0.551	0.870	0.226	0.392
Random: Voucher vs. No Voucher	0.710	0.934	0.645	0.671	0.773	0.054*

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. The outcome of columns (1) and (2) reports the percent of current network members with an iron sheets roof, as reported by the participant in the survey where she first mentioned that person as a part of her network. The outcome of columns (3) and (4) is an indicator for if at least half of the participant's current network members have an iron sheets roof, as reported by the participant in the survey where she first mentioned that person as a part of her network. The outcome of columns (5) is the number of people with an iron sheets roof in her baseline network who are no longer a part of her endline network, plus the number of people with an iron sheets roof in her endline network who were not a part of her baseline network. The outcome of columns (6) is the number of people with a thatched roof in her baseline network who are no longer a part of her endline network, plus the number of people with a thatched roof in her endline network who were not a part of her baseline network.

Table D.30: Food Security Index: Heterogeneity by Guest Age and Guest Networks

	(1)	(2)	(3)	(4)

Control Mean	6.019	0.078	331.126	0.306	0.216	0.249	0.606	87.441	35.516

Standard errors in parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$. All specifications include baseline unbalanced control variables (number of rented garden plots, and if the husband was listed in the baseline network), geographic cluster fixed effects, cluster-specific wealth quintile fixed effects, and lasso-selected controls. The outcome of column (1) is the total number of baseline network links who are not in the endline network, plus the total number of endline network links who are not in the baseline network. The outcome of column (2) is the food security index. The outcome of column (3) is total farm yields converted to US dollar value. The outcome of column (4) takes the value of 1 for participants who experienced mild-to-severe depressive symptoms at endline, and 0 otherwise. The outcome of column (5) takes the value of 1 for participants who, at midline, report that they earned income from self-employment in the past month, and 0 otherwise. The outcome of column (6) takes the value of 1 for participants who have any strong tie in the network who is a friend she met herself (not through her husband), and 0 otherwise. The outcome of column (7) is the number of people in the network who the respondent met herself (not through her husband) and with whom she says she shares secrets. The outcome of column (8) is the last harvest's legume yields converted to US dollar value. The outcome of column (9) is last harvest's cash crop yields converted to US dollar value. I estimate treatment effects separated for each of the three main treatment groups – Inviters with the High-SES Guest List, Inviters with the Low-SES Guest List, and Inviters with the Random Guest List – and each of their interaction with log-years that the participant has lived in the village plus 1. Participants who just arrived to the village are in their first year in the village, so log years in the village is log of 1 for these participants.

Appendix E Robustness

E.1 Populated Pre-Analysis Plan

Table E.1: Main Outcomes: Pre-Specified versus Paper

Main Outcomes	Pre- Specified Variable	Variable in Paper	Reasons for Deviations
Psychological well-being	(1) CESDR-10 score, (2) UCLA-3 score, (3) “is there someone you can talk to about a quarrel with your husband?”	CESDR-10 score ≥ 10	Variables (2) and (3) have little variation
Social capital	(1) Number of relatives in network, (2) Number of non-relatives in network, (3) Strength of relatives ties, (4) Strength of non-relative ties	Each variable is evaluated separately instead of together in an index as an outcome	It is not ex-ante clear which “types” of social capital we should expect to be correlated with one another, or with downstream outcomes
Savings and consumption	(1) Kilograms of maize in storage, (2) Participation in ROSCA or VSLA, (3) Number of meals eaten yesterday, (4) Number of meals eaten the day before yesterday, (5) Number of animal protein meals in the past month	Split into three variables: (1) Farm Yields, (2) Food Security Index, and (3) Potential for Risk-Sharing Index	Variables are conceptually distinct and represent different, individually interesting, economic strategies
Social Capital Definitions	Pre- Specified Variable	Variable in Paper	Reasons for Deviations
Strength of ties	(1) Inclusion of self-in-other score, (2) Trust in network connections, (3) Ability to laugh with network connection, (4) Comfort confiding in network connection	As described + “shares secrets with network connection”	Additional variable provides more variation, and helps identify right-tail emotionally strong ties.
Economic closeness of ties	(1) Comfort asking network connection to borrow money or goods, (2) Comfort lending money or goods to network connection	Both variables + “comfort both lending and borrowing with network connection” are included in the Potential for Risk-Sharing Index	Additional variable provides more variation, and helps identify right-tail economically strong ties.

Detailed Rationale for Changes in Psychological Well-Being Outcome: Variables (2) and (3) have significantly less variation than the CESDR-10 score. As such, I evaluate the CESDR-10 score on its own as the main outcome. The other variables move in the same direction, but when taken together as an index, they add more noise.

Detailed Rationale for Changes in Social Capital Outcome: It helps us understand downstream outcomes more to tease each component apart than to evaluate an overall social capital score. There are reasons to believe there could be substitution across types of social capital, or churn in social capital rather than an overall increase in the quantity or strength of ties.

Detailed Rationale for Changes in Savings and Consumption Outcome: The pre-specified index combines conceptually distinct items that are all geared towards understanding economic well-being. I replaced “maize stores” with “farm yields” because maize stores as an outcome combines both savings and choice of savings technology. Although farm yields are not verifiable, as with maize stores, it represents the simplest and most relevant proxy for income.

Detailed Rationale for Changes in Strength of Ties Outcome: The fifth variable was excluded in the pre-specified variable because it is collected in a different way than the other variables. However, it is positively correlated with the other variables, and because it is collected differently, tends to identify the fewer network members, thereby adding more information about the right-tail of emotional closeness.

Detailed Rationale for Changes in Economic Closeness Outcome: There are some people who respondents report comfort borrowing, others who they report comfort lending, and fewer for whom they report comfort both borrowing and lending. By including the combined measure, we learn more information about the right-tail of economic closeness.

E.2 Multiple Hypothesis Testing

To account for multiple hypothesis testing, I correct for the false discovery rate. I present FDR-sharpened q-values for a set of thirty hypotheses in Table E.4. Four of these tests are from the first stage, and twenty-eight tests are from the second stage. I test the effect of the Voucher among Inviters with the Random Guest List for three outcomes: if the Inviter sent any invitation, if she sent any invitation to a High-SES Guest, and if she sent any invitation to a Low-SES Guest. For the first outcome—if Inviters sent any invitation—I also test equality of the four other groups (Inviters with the High-SES Guest List or Low-SES Guest List, with or without the Voucher). For eleven downstream outcomes, I test two hypotheses each: the pooled Inviter treatment effect relative to the Control group, and the treatment effect among Inviters with the High-SES Guest List relative to the treatment effect among Inviters with the Low-SES Guest List. The outcomes I include in the family include the three main downstream outcomes (the food security index, farm yields in USD value, and mild-to-severe depression), and a representative outcome from each of the primary drivers of these outcomes that I test: self-employment in the past month (at midline and endline), an indicator for growing cash crops (endline), the potential for risk-sharing index (endline), the number of borrowers in the past year (endline), whether or not the Inviter borrowed from anyone in the past six months (endline), network degree (endline), network churn (endline), the churn of husband’s relatives in the network (endline), and loneliness (an indicator for if the UCLA-3 score is ≥ 6 , measured at endline).

The main first-stage effect remains statistically significant: Inviters with the Random Guest List are more likely to send invitations to High-SES Guests with the Voucher than without the Voucher (q-value = 0.089). The effects on the main outcomes also remain statistically significant, both when pooled and compared with the Control group, and when comparing Inviters with the Low-SES Guest List and Inviters with the High-SES Guest List with one another. Almost all of the tests that are statistically significant in the main analysis remain statistically significant after correcting for the false discovery rate. The only exception is that the differential effect on self-employment between Inviters with the High-SES Guest List and Inviters with the Low-SES Guest List, measured at endline, is marginally no longer statistically significant at conventional levels (q-value = 0.113) (the effect measured at midline remains statistically significant, both when considering the pooled effect relative to the Control group and the differential effect among Inviters with the High-SES Guest List and Inviters with the Low-SES Guest List).

Appendix F Model Appendix

F.1 Model Predictions and Empirical Tests

Each of the following tests maps directly to a theoretical prediction, using the coefficients estimated in Equations 1–4 to empirically evaluate Lemma F.2 and Proposition 6.1(a)-(b). I additionally use the following two specifications, whose results are in Appendix Table C.2:

$$I_i^{H-only} = \beta_0^{H-only} + \beta_1^{H-only} T_i^{R,V} + \beta_2^{H-only} T_i^{H,NV} + \beta_3^{H-only} T_i^{H,V} X_i + \delta_i + \gamma_i + \epsilon_i \quad (6)$$

$$I_i^{L-only} = \beta_0^{L-only} + \beta_1^{L-only} T_i^{R,V} + \beta_2^{L-only} T_i^{L,NV} + \beta_3^{L-only} T_i^{L,V} + X_i + \delta_i + \gamma_i + \epsilon_i \quad (7)$$

where I_i^{H-only} takes the value of 1 if an Inviter sends an invitation to a High-SES Guest and sends no invitations to any Low-SES Guests; and I_i^{L-only} takes the value of 1 if an Inviter sends an invitation to a Low-SES Guest and sends no invitations to any High-SES Guests. These specifications are estimated only among Inviters with the Random Guest List.

I use Inviters' decisions about who to send invitations to, across treatment conditions, as a revealed preference measure of how Inviters perceive the returns to within-SES and cross-SES relationships, given different feasible levels of financial investment in the relationship.

Evaluating Model Assumptions

Model Assumption 6.1: Each Type has an Absolute Advantage

Interactions with one type is better at generating instrumental utility returns, and interactions with the other type is better at generating intrinsic utility returns.

Test: Inviters with the High-SES Guest List have greater second-stage treatment effects on some outcomes than Inviters with the Low-SES Guest List; and Inviters with the Low-SES Guest List have greater second-stage treatment effects on other outcomes than Inviters with the High-SES Guest List

Model Lemma F.2: Subsidies Induce Diversification

Interactions with high-SES and low-SES women generate different types of benefits, which agents both value, so agents seek economic diversity in their networks (this allows them to achieve more diversity in the potential benefits of their social interactions). Consequently, the marginal returns to a subsidy are large for mixed bundles faster than they are for homogeneous bundles [Proposition F.2]

Test: $\beta_1^{H\&L} > \beta_1^{H-only}$ and $\beta_1^{H\&L} > \beta_1^{L-only}$ (Equations 4, 6 and 7)

Among Inviters with the Random Guest List, the Voucher increases the probability of selecting a mixed bundle to a greater extent than it increases the probability of selecting a High-SES-only bundle, or a Low-SES-only bundle.

Model Predictions in the Experiment

Model Proposition 6.1: Diversification conditional on the zero-subsidy counterfactual

Agents will be most likely to invest more in the type whose returns are more sensitive to financial investment in response to a subsidy. Thus, if the benefits of cross-SES (within-SES) relationships are more sensitive to financial investment than the benefits of within-SES (cross-SES) relationships, then prices constrain cross-SES (within-SES) linking [Proposition 6.1(a)]. Crucially, this is because the rate of substitution between initiating links within-SES and across-SES changes with the price of investment, and so we should not expect to see the same when substitution is not an option [Proposition 6.1(b)].

Test: $\beta_1^H > 0$ or $\beta_1^L > 0$, and $\beta_2 = \beta_3 = \beta_4 = \beta_5$ (Equations 1 and 2)

- $\beta_1^H > 0 \Rightarrow$ high prices of social interaction contribute to income-based homophily
- $\beta_1^L > 0 \Rightarrow$ high prices of social interaction contribute to economic connectedness

Among Inviters with the Random Guest List, the Voucher increases the probability of inviting either High-SES or Low-SES women. Inviters with the High-SES Guest List and Low-SES Guest List invite women at the same rate, with or without the Voucher.

This test determines if prices inhibits linking with specific types of people, which generates broader implications for network composition by income.

Ruling out Alternate Models

My model rests on the assumption that women face trade-offs between the intrinsic utility benefits of low-SES interactions and the financial benefits of high-SES interactions, and that the returns and thus this trade-off are sensitive to financial investment in the interaction. This implies that linking patterns that appear as either an intrinsic preference for homophily or a state-independent constraint from forming links across-SES are actually an optimal price response.

I can test alternate models where effort costs and prices impose feasibility constraints. I describe two alternate tests and the models they imply below:

- $\beta_2 > \beta_4$ (Equation 1) *Without the Voucher, Inviters with the High-SES Guest List send fewer invitations than Inviters with the Low-SES Guest List:* Holding returns constant, the cost of effortful initiation with high-SES women constrains cross-SES relationships

- $\beta_1^H > 0$ and $\beta_3 - \beta_2 > \beta_5 - \beta_4$ (Equations 1 and 2) *The Voucher increases invitations to high-SES women among Inviters with the High-SES Guest List and Inviters with the Random Guest List, more so than it increases invitations to low-SES Guests among Inviters with the Low-SES Guest List: High prices constrain cross-SES relationships because high-SES links are infeasible without financial investment*

Table F.1: Model Tests

Returns to Economic Diversity			
Test	Coefs.	Interpretation	Table
$\checkmark$ (1) $\beta_1^{H\&L} - \beta_1^{L-only} > 0$, and	0.202***	$\checkmark$ Agents value the benefits of both types	Table C.3, Col. 2
$\checkmark$ (2) $\beta_1^{H\&L} - \beta_1^{H-only} > 0$	0.128**	$\checkmark$ Subsidies induce diversification	Table C.3, Col. 3
Understanding Homophily			
Test	Coefs.	Interpretation	Table
$\times \beta_2 - \beta_4 > 0$	-0.052	$\times$ Effort costs do not differentially constrain cross-SES linking	Table 1, Col. 1
$\checkmark$ (1) $\beta_1^H > 0$, and	0.085**	$\checkmark$ Price constrains cross-SES linking $\times$ Price is not a feasibility constraint $\checkmark$ Price variation drives substitution $\Rightarrow$ Trade-off between within-SES and cross-SES linking changes with price	Table 1, Col. 3
$\times$ (2) $(\beta_3 - \beta_2) - (\beta_5 - \beta_4) > 0$	0.002		Table 1, Col. 1
$\checkmark$ (3) $\beta_3 = \beta_2 = \beta_5 = \beta_4$	$p = 0.432$		Table 1, Col. 1
$\times \beta_1^H - \beta_1^L > 0$	0.073	$\bigcirc$ High prices might constrain economic connectedness overall	Table 1, Col. 2/3

Notes: This table presents a series of empirical tests that validate assumptions and predictions of the model. Column (1) presents the empirical test, using notation from the empirical specifications outlined in Section 3.4. Column (2) presents the coefficient from the model test in column (1). Column (3) interprets these coefficients, and column (4) references the tables where the coefficients in column (2) are reported. Appendix Section F.1 outlines the relationship between the model predictions and empirical tests in more detail. The $\checkmark$ symbol denotes tests where we can reject the null, the $\times$ symbol denotes tests where we cannot reject the null, and the $\bigcirc$ symbol denotes tests where the result is unclear. The last test is determined to be unclear because, while I cannot reject the null, the test is under-powered.

F.2 Model Proofs

Assumption F.1 (Each type has an absolute advantage in producing one type of utility). *Without loss of generality, denote types H and L with θ and θ' . Let θ be the type that is relatively more productive in generating a financial return, and let θ' be the type that is relatively more productive in generating intrinsic utility.*

1. For any fixed number of invitations $s \in \{0, 1\}$, and for every fixed level of investment $\bar{I} \in [0, 1]$:

$$\mathbb{V}(S_\theta = s + 1, S_{\theta'} = s, \bar{I}) > \mathbb{V}(S_\theta = s, S_{\theta'} = s + 1, \bar{I})$$

$$\mathbb{V}(S_\theta = s + 1, S_{\theta'} = s, \bar{I}) < \mathbb{V}(S_\theta = s, S_{\theta'} = s + 1, \bar{I})$$

2. Furthermore, the marginal benefit of the second θ type has no additional advantage in producing $\mathbb{V}$ when paired with another θ -type, relative to when paired with a θ' -type (and the symmetric condition for θ'). For any fixed level of investment $\bar{I} \in [0, 1]$:

$$\mathbb{V}(S_\theta = 1, S_{\theta'} = 1, \bar{I}) - \mathbb{V}(S_\theta = 1, S_{\theta'} = 0, \bar{I}) \geq \mathbb{V}(S_\theta = 0, S_{\theta'} = 2, \bar{I}) - \mathbb{V}(S_\theta = 0, S_{\theta'} = 1, \bar{I})$$

$$\mathbb{V}(S_\theta = 1, S_{\theta'} = 1, \bar{I}) - \mathbb{V}(S_\theta = 0, S_{\theta'} = 1, \bar{I}) \geq \mathbb{V}(S_\theta = 2, S_{\theta'} = 0, \bar{I}) - \mathbb{V}(S_\theta = 1, S_{\theta'} = 0, \bar{I})$$

Lemma F.1. (Conditions for a Preference for Diversity) Define λ_Y and λ_V as value-weights on consumption and intrinsic utility of relationships, respectively, in the agent's total utility function:

$$\lambda_Y = \frac{\partial U}{\partial Z} \cdot \frac{\partial Z}{\partial \mathbb{Y}} > 0, \quad \lambda_V = \frac{\partial U}{\partial \mathbb{V}} > 0$$

Given a fixed investment level $\bar{I} \in [0, 1]$, a diverse set of two invitations (i.e., $(S_L, S_H) = (1, 1)$) is more “productive” than a concentrated set of two invitations (i.e., $(S_L, S_H) \in \{(2, 0), (0, 2)\}$) whenever:

$$\frac{\lambda_Y}{\lambda_V} \in \begin{cases} \left(\frac{\mathbb{V}(0, 2, \bar{I}) - \mathbb{V}(1, 1, \bar{I})}{\mathbb{Y}(1, 1, \bar{I}) - \mathbb{Y}(0, 2, \bar{I})}, \frac{\mathbb{V}(1, 1, \bar{I}) - \mathbb{V}(2, 0, \bar{I})}{\mathbb{Y}(2, 0, \bar{I}) - \mathbb{Y}(1, 1, \bar{I})} \right) & \text{if } \mathbb{Y}(2, 0, \bar{I}) - \mathbb{Y}(1, 1, \bar{I}) > 0 \\ \left(\frac{\mathbb{V}(0, 2, \bar{I}) - \mathbb{V}(1, 1, \bar{I})}{\mathbb{Y}(1, 1, \bar{I}) - \mathbb{Y}(0, 2, \bar{I})}, \infty \right) & \text{if } \mathbb{Y}(2, 0, \bar{I}) - \mathbb{Y}(1, 1, \bar{I}) \leq 0 \end{cases} \quad (8)$$

where λ_Y and λ_V are held fixed, but evaluated locally for the comparison between a concentrated and diversified bundle.

Lemma F.2 (Subsidies induce diversification.). Assume that $\lambda_Y/\lambda_V \in P$ for all I . As-

sume that the difference between c_θ and $c_{\theta'}$ is bounded so that

$$c_\theta - c_{\theta'} \in \left(\max_{I \in [0,1]} -\frac{\lambda_Y}{\lambda_V} (\mathbb{Y}(1, 1, I) - \mathbb{Y}(2, 0, I)) - (\mathbb{V}(1, 1, I) - \mathbb{V}(2, 0, I)) , \right. \\ \left. \min_{I \in [0,1]} \frac{\lambda_Y}{\lambda_V} (\mathbb{Y}(1, 1, I) - \mathbb{Y}(0, 2, I)) + (\mathbb{V}(1, 1, I) - \mathbb{V}(0, 2, I)) \right) \quad (9)$$

Define τ^+ as the minimal subsidy large enough to induce an increase in initiations. This τ^+ exists if $S_\theta^*(0) + S_{\theta'}^*(0) < 2$. Then, for any $\tau > \tau^+$:

$$S_\theta^*(\tau) < 2 \quad \text{and} \quad S_{\theta'}^*(\tau) < 2$$

When $\lambda_Y/\lambda_V \in P$ (the preference space where diverse invitation sets generate a larger return than concentrated invitation sets), and when the difference between the fixed effort costs is bound, a subsidy large enough to induce an increase in initiations will induce more diversity in the set of initiations.

Define $R(S_L, S_H, I)$ as the total weighted returns from relationship initiation and investment decisions, net of effort costs:

$$R(S_L, S_H, I) := \lambda_Y \mathbb{Y}(S_L, S_H, I) + \lambda_V (\mathbb{V}(S_L, S_H, I) - S_L c_L - S_H c_H).$$

Assumption F.2 (One type is more responsive to investment). *Without loss of generality, assume that returns to interaction with the θ -type benefit relatively more from investment than the θ' -type, at all feasible bundles.*

For a fixed $s \in \{0, 1\}$, and a fixed $s' \in \{1, 2\}$, with $s + s' \leq 2$:

$$\frac{\partial}{\partial I} (R(S_\theta = s', S_{\theta'} = s, I) - R(S_\theta = 0, S_{\theta'} = s, I)) \\ > \frac{\partial}{\partial I} (R(S_\theta = s, S_{\theta'} = s', I) - R(S_\theta = s, S_{\theta'} = 0, I)) \quad (10)$$

Assumption F.3 (Heterogeneous Preference Weights Cannot Overturn Each Type's Advantage).

$$\frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} (\mathbb{V}(0, 1, I_{g_1}^*(0)) + c_\theta) - \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} (\mathbb{V}(1, 0, I_{g_2}^*(0)) + c_{\theta'}) \geq \left(\frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} - \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} \right) \mathbb{V}(1, 1, I), \quad (11)$$

The complementarity between the two types is bound so that, among people who prefer financial return, there is an intrinsic utility advantage to initiating relationships with θ' -types.

Defining Prohibitively High Effort Costs

Let $\mathcal{T} \subset \mathbb{R}$ denote the support of the subsidy τ , and define $p_{\min} := \inf_{\tau \in \mathcal{T}} (p^I - \tau)$. Then $S_\theta = 0$ across all levels of $S_{\theta'}$, τ , and I whenever $c_\theta > \bar{c}_\theta$, where:

$$\bar{c}_\theta = \sup_{g \in \{g_1, g_2\}} \sup_{s' \in \{0, 1\}} \sup_{I \in [0, 1]} \left[\frac{\lambda_Y^g}{\lambda_V^g} (\mathbb{Y}(1, s', I) - \mathbb{Y}(0, s', I)) + (\mathbb{V}(1, s', I) - \mathbb{V}(0, s', I)) - \frac{\lambda_Y^g}{\lambda_V^g} p_{\min} I \right]. \quad (12)$$

Proof of Lemma F.1. From F.1:

$$\begin{aligned} \mathbb{Y}(S_\theta = 1, S_{\theta'} = 1, \bar{I}) - \mathbb{Y}(S_\theta = 1, S_{\theta'} = 0, \bar{I}) &\geq \mathbb{Y}(S_\theta = 0, S_{\theta'} = 2, \bar{I}) - \mathbb{Y}(S_\theta = 0, S_{\theta'} = 1, \bar{I}) \\ \iff \mathbb{Y}(S_\theta = 1, S_{\theta'} = 1, \bar{I}) - \mathbb{Y}(S_\theta = 0, S_{\theta'} = 2, \bar{I}) &\geq \mathbb{Y}(S_\theta = 1, S_{\theta'} = 0, \bar{I}) - \mathbb{Y}(S_\theta = 0, S_{\theta'} = 1, \bar{I}) \\ &> 0 \quad \text{by Assumption F.1 point (1)} \end{aligned}$$

These conditions imply that:

$$\begin{aligned} \mathbb{Y}(S_\theta = 1, S_{\theta'} = 1, I) &> \mathbb{Y}(S_\theta = 0, S_{\theta'} = 2, I) \quad \text{and} \\ \mathbb{V}(S_\theta = 1, S_{\theta'} = 1, I) &> \mathbb{V}(S_\theta = 2, S_{\theta'} = 0, I) \quad \text{by symmetry} \end{aligned}$$

We can denote the total returns to social relationships as:

$$\mathbb{R}(S_L, S_H, I) = \lambda_Y \mathbb{Y}(S_L, S_H, I) + \lambda_V \mathbb{V}(S_L, S_H, I)$$

We want to find a region of preferences where $\mathbb{R}(1, 1, I) > \mathbb{R}(2, 0, I)$ and $\mathbb{R}(1, 1, I) > \mathbb{R}(0, 2, I)$.

$$\begin{aligned} \mathbb{R}(1, 1, I) &> \mathbb{R}(2, 0, I) \\ \iff \lambda_Y \mathbb{Y}(1, 1, I) + \lambda_V \mathbb{V}(1, 1, I) &> \lambda_Y \mathbb{Y}(2, 0, I) + \lambda_V \mathbb{V}(2, 0, I) \\ \iff \lambda_V (\mathbb{V}(1, 1, I) - \mathbb{V}(2, 0, I)) &> \lambda_Y (\mathbb{Y}(2, 0, I) - \mathbb{Y}(1, 1, I)) \\ \frac{\lambda_V}{\lambda_Y} &> \frac{\mathbb{Y}(2, 0, I) - \mathbb{Y}(1, 1, I)}{\mathbb{V}(1, 1, I) - \mathbb{V}(2, 0, I)} \end{aligned}$$

$$\begin{aligned} \mathbb{R}(1, 1, I) &> \mathbb{R}(0, 2, I) \\ \iff \lambda_Y \mathbb{Y}(1, 1, I) + \lambda_V \mathbb{V}(1, 1, I) &> \lambda_Y \mathbb{Y}(0, 2, I) + \lambda_V \mathbb{V}(0, 2, I) \\ \iff \lambda_Y (\mathbb{Y}(1, 1, I) - \mathbb{Y}(0, 2, I)) &> \lambda_V (\mathbb{V}(0, 2, I) - \mathbb{V}(1, 1, I)) \\ \frac{\lambda_Y}{\lambda_V} &> \frac{\mathbb{V}(0, 2, I) - \mathbb{V}(1, 1, I)}{\mathbb{Y}(1, 1, I) - \mathbb{Y}(0, 2, I)} \end{aligned}$$

Note that the denominator of the lower-bound on λ_Y/λ_V is always positive. If $\mathbb{Y}(2, 0, I) - \mathbb{Y}(1, 1, I) > 0$, then we can arrange the lower bound on λ_V/λ_Y to obtain an upper bound

on λ_Y/λ_V :

$$\frac{\lambda_Y}{\lambda_V} < \frac{\mathbb{V}(1, 1, I) - \mathbb{V}(2, 0, I)}{\mathbb{V}(2, 0, I) - \mathbb{V}(1, 1, I)}$$

If $\mathbb{V}(2, 0, I) - \mathbb{V}(1, 1, I) \leq 0$, then $\mathbb{R}(1, 1, I) > \mathbb{R}(2, 0, I)$ holds for all $\lambda_Y/\lambda_V > 0$, so the upper bound is effectively $+\infty$. $\square$

Proof of Lemma F.2. Fix $\tau \in \mathbb{R}$ and write $p(\tau) := p^I - \tau$. Using $Z = \bar{y} + \mathbb{V}(S_L, S_H, I) - p(\tau) I(S_L + S_H)$, the problem at subsidy τ is equivalent to

$$\max_{(S_L, S_H) \in \{(0,0), (1,0), (0,1), (2,0), (0,2), (1,1)\}, I \in [0,1]} R(S_L, S_H, I) - \lambda_Y p(\tau) I(S_L + S_H).$$

Let $(S_L^*(0), S_H^*(0), I^*(0))$ be an optimizer at $\tau = 0$. Set

$$\begin{aligned} \tau^+ &:= \inf \left\{ \tau \in \mathbb{R} : \max_{\substack{(S_L, S_H) \in \{(0,0), (1,0), (0,1), (2,0), (0,2), (1,1)\} \\ I \in [0,1] \\ S_L + S_H > S_L^*(0) + S_H^*(0)}} \left[R(S_L, S_H, I) - \lambda_Y p(\tau) I(S_L + S_H) \right] \right. \\ &\quad \left. \geq \max_{\substack{(S_L, S_H) \in \{(0,0), (1,0), (0,1), (2,0), (0,2), (1,1)\} \\ I \in [0,1] \\ S_L + S_H = S_L^*(0) + S_H^*(0)}} \left[R(S_L, S_H, I) - \lambda_Y p(\tau) I(S_L + S_H) \right] \right\}, \end{aligned}$$

Now I show the existence of such a τ^+ . For any fixed (S_L, S_H, I) , define

$$F(S_L, S_H, I; \tau) := R(S_L, S_H, I) - \lambda_Y (p^I - \tau) I(S_L + S_H).$$

Then

$$\frac{\partial}{\partial \tau} F(S_L, S_H, I; \tau) = \lambda_Y I(S_L + S_H).$$

At the baseline choice $(S_L^*(0), S_H^*(0), I^*(0))$ this derivative equals

$$\lambda_Y I^*(0) (S_L^*(0) + S_H^*(0)).$$

If $S_L^*(0) + S_H^*(0) < 2$, then there exists a feasible $(\tilde{S}_L, \tilde{S}_H, 1)$ with $\tilde{S}_L + \tilde{S}_H > S_L^*(0) + S_H^*(0)$. For this choice,

$$\frac{\partial}{\partial \tau} F(\tilde{S}_L, \tilde{S}_H, 1; \tau) = \lambda_Y (\tilde{S}_L + \tilde{S}_H) > \lambda_Y I^*(0) (S_L^*(0) + S_H^*(0)).$$

Since $I^*(0) \leq 1$. Therefore

$$\frac{\partial}{\partial \tau} F(\tilde{S}_L, \tilde{S}_H, 1; \tau) > \frac{\partial}{\partial \tau} F(S_L^*(0), S_H^*(0), I^*(0); \tau).$$

Define the difference

$$D(\tau) := F(\tilde{S}_L, \tilde{S}_H, 1; \tau) - F(S_L^*(0), S_H^*(0), I^*(0); \tau).$$

This is an affine function of τ with

$$\frac{d}{d\tau} D(\tau) > 0.$$

Hence $D(\tau)$ is strictly increasing in τ . Because $D(0) \leq 0$ (the baseline bundle is optimal at $\tau = 0$), it follows that there exists some finite τ with $D(\tau) > 0$. At such a τ , the bundle with $\tilde{S}_L + \tilde{S}_H > S_L^*(0) + S_H^*(0)$ yields strictly higher utility than the baseline bundle. By definition, the smallest such value of τ is τ^+ .

By the definition of τ^+ , for any $\tau > \tau^+$,

$$\begin{aligned} \max_{\substack{S_L + S_H > S_L^*(0) + S_H^*(0) \\ I \in [0,1]}} \left[R(S_L, S_H, I) - \lambda_Y p(\tau) I(S_L + S_H) \right] &> \\ \max_{\substack{S_L + S_H = S_L^*(0) + S_H^*(0) \\ I \in [0,1]}} \left[R(S_L, S_H, I) - \lambda_Y p(\tau) I(S_L + S_H) \right]. \end{aligned}$$

Hence any optimizer at $\tau > \tau^+$ satisfies $S_L^*(\tau) + S_H^*(\tau) > S_L^*(0) + S_H^*(0)$.

Fix $\tau > \tau^+$ and suppose $S_L^*(\tau) + S_H^*(\tau) = 2$. Let $I_{2,0}^*(\tau) \in \arg \max_{I \in [0,1]} \{R(2, 0, I) - 2\lambda_Y p(\tau) I\}$, and define $I_{0,2}^*(\tau)$ analogously. Then

$$(R(1, 1, I_{2,0}^*(\tau)) - 2\lambda_Y p(\tau) I_{2,0}^*(\tau)) - (R(2, 0, I_{2,0}^*(\tau)) - 2\lambda_Y p(\tau) I_{2,0}^*(\tau)) = R(1, 1, I_{2,0}^*(\tau)) - R(2, 0, I_{2,0}^*(\tau)).$$

By Lemma F.1, we know that for all I ,

$$\lambda_Y (\mathbb{Y}(1, 1, I) - \mathbb{Y}(2, 0, I)) + \lambda_V (\mathbb{W}(1, 1, I) - \mathbb{W}(2, 0, I)) > 0.$$

With the cost-bounds assumption (9), the additional term $\lambda_V (c_\theta - c_{\theta'})$ does not overturn this inequality, so that

$$R(1, 1, I) - R(2, 0, I) > 0 \quad \text{for all } I \in [0, 1].$$

Therefore, in particular,

$$R(1, 1, I_{2,0}^*(\tau)) - R(2, 0, I_{2,0}^*(\tau)) > 0.$$

The same argument shows the $(1, 1)$ bundle strictly dominates $(0, 2)$ at τ . Therefore, if

$S_L^*(\tau) + S_H^*(\tau) = 2$, the unique maximizer has $(S_L^*(\tau), S_H^*(\tau)) = (1, 1)$, so

$$S_L^*(\tau) < 2 \quad \text{and} \quad S_H^*(\tau) < 2.$$

□

Proof of Proposition 6.1(a). Let $I_0 := I_{g_1}^*(0) = I_{g_2}^*(0)$. For each group $g \in \{g_1, g_2\}$, define the rescaled return function

$$\widehat{R}_g(S_\theta, S_{\theta'}, I) := \frac{1}{\lambda_Y^g} R(S_\theta, S_{\theta'}, I).$$

Then, for any $I \in [I_0, 1]$, define

$$\widehat{f}_{g_1}(I) := p^I - \frac{\widehat{R}_{g_1}(1, 1, I) - \widehat{R}_{g_1}(0, 1, I_0)}{2I - I_0}, \quad \widehat{f}_{g_2}(I) := p^I - \frac{\widehat{R}_{g_2}(1, 1, I) - \widehat{R}_{g_2}(1, 0, I_0)}{2I - I_0}.$$

Let

$$\bar{I} \in \arg \min_{I \in [I_0, 1]} \widehat{f}_{g_1}(I)$$

By definition

$$\tau_{g_1}^+ := \inf_{I \in [I_0, 1]} \widehat{f}_{g_1}(I) = \widehat{f}_{g_1}(\bar{I}), \quad \tau_{g_2}^+ := \inf_{I \in [I_0, 1]} \widehat{f}_{g_2}(I).$$

By continuity of I on the compact interval $[I_0, 1]$, the minima exist.

Because g_1 is defined as the group who selects $S_\theta^*(0) = 0, S_{\theta'}^*(0) = 1$ in the zero-subsidy counterfactual, and g_2 is defined as the group who selects $S_\theta^*(0) = 1, S_{\theta'}^*(0) = 0$ in the zero-subsidy counterfactual, for these to be optimal choice sets it must be that $\lambda_V^{g_1}/\lambda_Y^{g_1} > \lambda_V^{g_2}/\lambda_Y^{g_2}$. This implies that, for $\tilde{I} > I_0$:

$$\begin{aligned} & \frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} ((\mathbb{V}(1, 1, \tilde{I}) - c_\theta - c_{\theta'}) - (\mathbb{V}(1, 1, I_0) - c_\theta - c_{\theta'})) \\ & > \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} ((\mathbb{V}(1, 1, \tilde{I}) - c_\theta - c_{\theta'}) - (\mathbb{V}(1, 1, I_0) - c_\theta - c_{\theta'})) \end{aligned}$$

because both sides are positive since $\mathbb{V}(\cdot)$ increasing in I . Then, adding terms and

simplifying both sides:

$$\begin{aligned}
& \mathbb{V}(1, 1, \tilde{I}) - \mathbb{V}(1, 1, I_0) + \frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} ((\mathbb{V}(1, 1, \tilde{I}) - c_\theta - c_{\theta'}) - (\mathbb{V}(1, 1, I_0) - c_\theta - c_{\theta'})) \\
& > \mathbb{V}(1, 1, \tilde{I}) - \mathbb{V}(1, 1, I_0) + \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} ((\mathbb{V}(1, 1, \tilde{I}) - c_\theta - c_{\theta'}) - (\mathbb{V}(1, 1, I_0) - c_\theta - c_{\theta'})) \\
\implies & \frac{1}{\lambda_Y^{g_1}} (R_{g_1}(1, 1, \tilde{I}) - R_{g_1}(1, 1, I_0)) > \frac{1}{\lambda_Y^{g_2}} (R_{g_2}(1, 1, \tilde{I}) - R_{g_2}(1, 1, I_0)) \\
& \implies \widehat{R}_{g_1}(1, 1, \tilde{I}) - \widehat{R}_{g_1}(1, 1, I_0) > \widehat{R}_{g_2}(1, 1, \tilde{I}) - \widehat{R}_{g_2}(1, 1, I_0) \\
& \implies [\widehat{R}_{g_1}(1, 1, \tilde{I}) - \widehat{R}_{g_1}(0, 1, I_0)] + [\widehat{R}_{g_1}(0, 1, I_0) - \widehat{R}_{g_1}(1, 1, I_0)] \\
& \quad > [\widehat{R}_{g_2}(1, 1, \tilde{I}) - \widehat{R}_{g_2}(1, 0, I_0)] + [\widehat{R}_{g_2}(1, 0, I_0) - \widehat{R}_{g_2}(1, 1, I_0)]
\end{aligned}$$

Note that

$$\begin{aligned}
& \widehat{R}_{g_2}(1, 1, I_0) - \widehat{R}_{g_2}(1, 0, I_0) \geq \widehat{R}_{g_1}(1, 1, I_0) - \widehat{R}_{g_1}(0, 1, I_0) \\
\implies & \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} (\mathbb{V}(1, 1, I_0) - \mathbb{V}(1, 0, I_0) - c_{\theta'}) \geq \mathbb{V}(1, 0, I_0) - \mathbb{V}(0, 1, I_0) \\
& \quad + \frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} (\mathbb{V}(1, 1, I_0) - \mathbb{V}(0, 1, I_0) - c_\theta) \\
\implies & \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} (\mathbb{V}(1, 1, I_0) - \mathbb{V}(1, 0, I_0) - c_{\theta'}) \geq \frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} (\mathbb{V}(1, 1, I_0) - \mathbb{V}(0, 1, I_0) - c_\theta) \\
\implies & \frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} (\mathbb{V}(0, 1, I_0) + c_\theta) - \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} (\mathbb{V}(1, 0, I_0) + c_{\theta'}) \geq \left(\frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} - \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} \right) \mathbb{V}(1, 1, I_0)
\end{aligned}$$

Which is true by Equation 11. This implies that, $\forall \tilde{I} > I_0$,

$$\widehat{R}_{g_1}(1, 1, \tilde{I}) - \widehat{R}_{g_1}(0, 1, I_0) > \widehat{R}_{g_2}(1, 1, \tilde{I}) - \widehat{R}_{g_2}(1, 0, I_0).$$

By Assumption F.2,

$$\frac{\partial}{\partial I} (\widehat{R}_{g_1}(1, 1, I) - \widehat{R}_{g_1}(0, 1, I)) > \frac{\partial}{\partial I} (\widehat{R}_{g_1}(1, 1, I) - \widehat{R}_{g_1}(1, 0, I))$$

Decomposing each side and using the fact that $\lambda_V^{g_1}/\lambda_Y^{g_1} > \lambda_V^{g_2}/\lambda_Y^{g_2}$:

$$\begin{aligned}
&\Rightarrow \frac{1}{\lambda_Y^{g_1}} \cdot \frac{\partial}{\partial I} (\lambda_Y^{g_1} (\mathbb{Y}(1, 1, I) - \mathbb{Y}(0, 1, I)) + \lambda_V^{g_1} (\mathbb{V}(1, 1, I) - \mathbb{V}(0, 1, I) - c_{\theta})) \\
&\quad > \frac{\partial}{\partial I} (\widehat{R}_{g_1}(1, 1, I) - \widehat{R}_{g_1}(1, 0, I)) \\
&\quad = \frac{\partial}{\partial I} (\mathbb{Y}(1, 1, I) - \mathbb{Y}(1, 0, I)) + \frac{\lambda_V^{g_1}}{\lambda_Y^{g_1}} \cdot \frac{\partial}{\partial I} (\mathbb{V}(1, 1, I) - \mathbb{V}(1, 0, I) - c_{\theta'}) \\
&\quad > \frac{\partial}{\partial I} (\mathbb{Y}(1, 1, I) - \mathbb{Y}(1, 0, I)) + \frac{\lambda_V^{g_2}}{\lambda_Y^{g_2}} \cdot \frac{\partial}{\partial I} (\mathbb{V}(1, 1, I) - \mathbb{V}(1, 0, I) - c_{\theta'}) \\
&\quad = \frac{\partial}{\partial I} (\widehat{R}_{g_2}(1, 1, I) - \widehat{R}_{g_2}(1, 0, I)) \\
&\Rightarrow \frac{\partial}{\partial I} (\widehat{R}_{g_1}(1, 1, I) - \widehat{R}_{g_1}(0, 1, I)) > \frac{\partial}{\partial I} (\widehat{R}_{g_2}(1, 1, I) - \widehat{R}_{g_2}(1, 0, I))
\end{aligned}$$

For every $I \geq I_0$,

$$\widehat{f}_{g_2}(I) - \widehat{f}_{g_1}(I) = \frac{[\widehat{R}_{g_1}(1, 1, I) - \widehat{R}_{g_1}(0, 1, I_0)] - [\widehat{R}_{g_2}(1, 1, I) - \widehat{R}_{g_2}(1, 0, I_0)]}{2I - I_0} > 0, \quad (13)$$

because $2I - I_0 > 0$ for $I \geq I_0$. Taking infima over $I \in [I_0, 1]$ yields

$$\tau_{g_2}^+ = \inf_{I \in [I_0, 1]} \widehat{f}_{g_2}(I) \geq \inf_{I \in [I_0, 1]} \widehat{f}_{g_1}(I) = \tau_{g_1}^+. \quad (14)$$

Moreover, by continuity on the compact set $[I_0, 1]$, the function $I \mapsto \widehat{f}_{g_2}(I) - \widehat{f}_{g_1}(I)$ attains a positive minimum, so there exists $\varepsilon > 0$ with

$$\widehat{f}_{g_2}(I) \geq \widehat{f}_{g_1}(I) + \varepsilon \quad \text{for all } I \in [I_0, 1], \quad (15)$$

and hence

$$\tau_{g_2}^+ \geq \tau_{g_1}^+ + \varepsilon. \quad (16)$$

Fix any $\tau \in (\tau_{g_1}^+, \tau_{g_2}^+)$. By definition of $\tau_{g_1}^+$, there exists $I_1 \in [I_0, 1]$ with

$$\widehat{f}_{g_1}(I_1) < \tau \iff \widehat{R}_{g_1}(1, 1, I_1) - \widehat{R}_{g_1}(0, 1, I_0) > (2I_1 - I_0)p(\tau), \quad (17)$$

so group g_1 strictly benefits from adding the missing type at price $p(\tau) = p^I - \tau$. In contrast, since $\tau < \tau_{g_2}^+$,

$$\tau < \widehat{f}_{g_2}(I) \quad \text{for all } I \in [I_0, 1], \quad (18)$$

so group g_2 does not add the missing type at any feasible I .

Finally, because $\lambda_Y^g/\lambda_V^g \in P$ for all feasible I and the effort-cost difference is within the

bounds in (9), the diversified bundle (1, 1) strictly dominates the concentrated bundles (2, 0) and (0, 2) at I_1 by Lemma F.1. Hence under any $\tau \in (\tau_{g_1}^+, \tau_{g_2}^+)$:

- g_1 agents diversify from (0, 1) to (1, 1) at some $I_1 \geq I_0$,
- g_2 agents make no change from (1, 0),
- the number of θ -type initiations increases in the aggregate, while the number of θ' -type initiations is unchanged.

□

Proof of Proposition 6.1(b). Fix baseline costs $c^0 = (c_\theta^0, c_{\theta'}^0)$ with $c_\theta^0 = c_{\theta'}^0$. Let $\tau^* \in (\tau_{g_1}^+(c^0), \tau_{g_2}^+(c^0))$. Consider the prohibitive-cost *shock* c^1 defined as follows: for each agent k with group $g(k) \in \{g_1, g_2\}$, the post-shock effort-cost pair is

$$(c_\theta^k, c_{\theta'}^k) \in \{(c_\theta^1, c_{\theta'}^0), (c_\theta^0, c_{\theta'}^1)\}, \quad \text{with} \quad c_\theta^1 > \bar{c}_\theta, \quad c_{\theta'}^1 > \bar{c}_{\theta'},$$

so exactly one type is infeasible after the shock. The assignment of shocks is split evenly across agents (independently of group g), and *baseline allocations are equivalent* across the two halves: the shares at (0, 0), (1, 0), (0, 1) match.

Let $\hat{R}_g$ be as defined earlier, and let $I_0 := I_{g_1}^*(0) = I_{g_2}^*(0)$. For agent k (with group $g(k)$), define the *single-type* threshold subsidies at baseline costs c^0 :

$$\hat{\tau}_{1,k,(0)}^{(\theta)} := \inf_{I \in (0,1]} \left\{ p^I - \frac{\hat{R}_{g(k)}(1, 0, I; c^0) - \hat{R}_{g(k)}(0, 0, 0; c^0)}{I} \right\}, \quad (19)$$

$$\hat{\tau}_{2,k,(1)}^{(\theta)} := \inf_{2I > I_0} \left\{ p^I - \frac{\hat{R}_{g(k)}(2, 0, I; c^0) - \hat{R}_{g(k)}(1, 0, I_0; c^0)}{2I - I_0} \right\}, \quad (20)$$

$$\hat{\tau}_{2,k,(0)}^{(\theta)} := \inf_{I \in (0,1]} \left\{ p^I - \frac{\hat{R}_{g(k)}(2, 0, I; c^0) - \hat{R}_{g(k)}(0, 0, 0; c^0)}{2I} \right\}, \quad (21)$$

and analogously $\hat{\tau}_{1,k,(0)}^{(\theta')}$, $\hat{\tau}_{2,k,(1)}^{(\theta')}$, $\hat{\tau}_{2,k,(0)}^{(\theta')}$ with (1, 0), (2, 0) replaced by (0, 1), (0, 2), respectively. For (0, 0) baselines, the pair $(\hat{\tau}_{1,k,(0)}^{(\cdot)}, \hat{\tau}_{2,k,(0)}^{(\cdot)})$ yields 0/1/2 additional invitations without double counting, since by construction $\hat{\tau}_{2,k,(0)}^{(\cdot)} \geq \hat{\tau}_{1,k,(0)}^{(\cdot)}$.

Let the baseline state indicator be

$$B_{0,0}^k := \mathbf{1}\{s_0^k = (0, 0)\}, \quad B_{1,0}^k := \mathbf{1}\{s_0^k = (1, 0)\}, \quad B_{0,1}^k := \mathbf{1}\{s_0^k = (0, 1)\}.$$

For a θ -only agent after the shock, the induced change at subsidy τ is

$$\Delta S_\theta^k(\tau) = B_{0,0}^k \left(\mathbf{1}\{\tau \geq \hat{\tau}_{1,k,(0)}^{(\theta)}\} + \mathbf{1}\{\tau \geq \hat{\tau}_{2,k,(0)}^{(\theta)}\} \right) + B_{1,0}^k \mathbf{1}\{\tau \geq \hat{\tau}_{2,k,(1)}^{(\theta)}\}, \quad (22)$$

and for a θ' -only agent,

$$\Delta S_{\theta'}^k(\tau) = B_{0,0}^k \left(\mathbf{1}\{\tau \geq \hat{\tau}_{1,k,(0)}^{(\theta')}\} + \mathbf{1}\{\tau \geq \hat{\tau}_{2,k,(0)}^{(\theta')}\} \right) + B_{0,1}^k \mathbf{1}\{\tau \geq \hat{\tau}_{2,k,(1)}^{(\theta')}\}. \quad (23)$$

No changes when $2I \leq I_0$ for any τ . Optimality of $(1, 0, I_0)$ and $(0, 1, I_0)$ at $\tau = 0$ under c^0 implies, for all I ,

$$\hat{R}_g(2, 0, I) - \hat{R}_g(1, 0, I_0) \leq (2I - I_0) p^I, \quad \hat{R}_g(0, 2, I) - \hat{R}_g(0, 1, I_0) \leq (2I - I_0) p^I.$$

Hence, for any τ and any I with $2I \leq I_0$,

$$[\hat{R}_g(2, 0, I) - \hat{R}_g(1, 0, I_0)] - (p^I - \tau)(2I - I_0) \leq \tau(2I - I_0) \leq 0,$$

and analogously for $(0, 2)$. Therefore no change is ever profitable when $2I \leq I_0$, which justifies the domain $2I > I_0$ in (20) and its θ' analogue.

Ordering of single-type thresholds. For each move $m \in \{(1|0), (2|1), (2|0)\}$ and each agent k , define the per-unit (or per-increment) utility gains

$$\begin{aligned} \Phi_m^{\theta,k}(I) &:= \frac{\hat{R}_{g(k)}(\theta\text{-bundle at } m; I; c^0) - \hat{R}_{g(k)}(\text{baseline at } m; c^0)}{\text{units of } I \text{ at } m}, \\ \Phi_m^{\theta',k}(I) &:= \frac{\hat{R}_{g(k)}(\theta'\text{-bundle at } m; I; c^0) - \hat{R}_{g(k)}(\text{baseline at } m; c^0)}{\text{units of } I \text{ at } m}. \end{aligned}$$

Assumption F.2 and $c_\theta^0 = c_{\theta'}^0$ imply

$$\begin{aligned} \Phi_m^{\theta,k}(I) &\geq \Phi_m^{\theta',k}(I) \quad \text{for all feasible } I, \\ \Rightarrow \quad \hat{\tau}_{m,k}^{(\theta)} &= \inf_I \{p^I - \Phi_m^{\theta,k}(I)\} \leq \inf_I \{p^I - \Phi_m^{\theta',k}(I)\} = \hat{\tau}_{m,k}^{(\theta')}. \end{aligned} \quad (24)$$

That is, each θ single-type threshold is weakly lower than its θ' counterpart.

Aggregate comparison at τ^* . Let J be the set of θ -only agents and J^c the set of θ' -only agents after the shock; $|J| = |J^c|$ and baseline-state shares match by construction. Summing (22) over $k \in J$ and (23) over $k \in J^c$, and applying (24) state-by-state yields, for every τ (in particular for τ),

$$\sum_{k \in J} \Delta S_\theta^k(\tau) \geq \sum_{k \in J^c} \Delta S_{\theta'}^k(\tau). \quad (25)$$

Therefore, at the fixed τ^* , the aggregate increase in θ -type invitations is *weakly* larger than the aggregate increase in θ' -type invitations.

Equality cases. Equality in (25) occurs when τ^* is either strictly below all relevant single-type thresholds or weakly above all relevant single-type thresholds, namely

$$\tau^* < \begin{cases} \min\{\hat{\tau}_{1,k,(0)}^{(\theta)}, \hat{\tau}_{1,k,(0)}^{(\theta')}\}, & \text{if } s_0^k = (0, 0), \\ \min\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}, & \text{if } s_0^k = (1, 0), \\ \min\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}, & \text{if } s_0^k = (0, 1), \end{cases}$$

or

$$\tau^* \geq \begin{cases} \max\{\hat{\tau}_{1,k,(0)}^{(\theta)}, \hat{\tau}_{1,k,(0)}^{(\theta')}\}, & \text{if } s_0^k = (0, 0), \\ \max\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}, & \text{if } s_0^k = (1, 0), \\ \max\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}, & \text{if } s_0^k = (0, 1). \end{cases}$$

I now show that each of the six equality cases is feasible under the maintained assumptions by showing that a small, controlled change to the return function—“perturbations” that are allowable under the model assumptions—can allow $\hat{\tau}_{m,k}^\theta$ and $\hat{\tau}_{m,k}^{\theta'}$ to be greater or lesser than τ^* , without changing the key features of the model.

Consider a modified return function

$$\hat{R}_g^{(\eta,\gamma)}(S_\theta, S_{\theta'}, I) := \hat{R}_g(S_\theta, S_{\theta'}, I) - \eta I (S_\theta + S_{\theta'}) + \gamma I S_\theta S_{\theta'}, \quad (\text{D})$$

with parameters $\eta, \gamma \in \mathbb{R}$. The $-\eta$ term subtracts the same multiple of I for every single-type bundle, while the $+\gamma$ term only affects the mixed-type bundle (1, 1). On single-type bundles ($S_\theta S_{\theta'} = 0$), the γ -term vanishes, so the $-\eta$ term shifts *every* single-type threshold by exactly $+\eta$:

$$\hat{\tau}_{m,k}^{(\cdot)}(\eta, \gamma) = \hat{\tau}_{m,k}^{(\cdot)}(0, 0) + \eta, \quad m \in \{(1|0), (2|1), (2|0)\}. \quad (26)$$

This means that, by choosing $\eta > 0$, all subsidies required to induce an additional invitation increase, and by choosing $\eta < 0$, all subsidies required to induce an additional invitation decrease. The relative ordering described above is maintained, regardless of η .

Although agents can never choose a mixed bundle because of the effort-cost shock, note that we need to ensure that τ^* is still within the assumed interval that is defined using $(c_\theta^0, c_{\theta'}^0)$, where mixed bundles are feasible, for values of η and γ . Note that the perturbation shifts both groups' f_g by the same continuous function of (η, γ) :

$$f_g^{(\eta,\gamma)}(I) = p^I - \frac{\hat{R}_g^{(\eta,\gamma)}(1, 1, I) - \hat{R}_g^{(\eta,\gamma)}(0, 1, I_0)}{2I - I_0} = \left(p^I - \frac{\hat{R}_g(1, 1, I) - \hat{R}_g(0, 1, I_0)}{2I - I_0} \right) + \eta - \gamma \frac{I}{2I - I_0}.$$

Thus, both f_{g_1} and f_{g_2} move together under this shift. By continuity, regardless of η , we

can adjust γ so that the same τ^* still lies strictly between $\tau_{g_1}^+(c^0; \eta, \gamma)$ and $\tau_{g_2}^+(c^0; \eta, \gamma)$.

Case 1: $\tau^* < \min\{\hat{\tau}_{1,k,(0)}^{(\theta)}, \hat{\tau}_{1,k,(0)}^{(\theta')}\}$ when $s_0^k = (0, 0)$.

By (26), pick $\eta > \tau^* - \min\{\hat{\tau}_{1,k,(0)}^{(\theta)}(0, 0), \hat{\tau}_{1,k,(0)}^{(\theta')}(0, 0)\}$ so that $\tau^* < \min\{\hat{\tau}_{1,k,(0)}^{(\theta)}(\eta, \gamma), \hat{\tau}_{1,k,(0)}^{(\theta')}(\eta, \gamma)\}$. (For completeness: the same choice of η also ensures $\tau^* < \min\{\hat{\tau}_{2,k,(0)}^{(\theta)}(\eta, \gamma), \hat{\tau}_{2,k,(0)}^{(\theta')}(\eta, \gamma)\}$, so $(0, 0)$ agents add none.)

Case 2: $\tau^* < \min\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}$ when $s_0^k = (1, 0)$.

Choose $\eta > \tau^* - \min\{\hat{\tau}_{2,k,(1)}^{(\theta)}(0, 0), \hat{\tau}_{2,k,(1)}^{(\theta')}(0, 0)\}$ and use (26).

Case 3: $\tau^* < \min\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}$ when $s_0^k = (0, 1)$.

Same argument as Case 2.

Case 4: $\tau^* \geq \max\{\hat{\tau}_{1,k,(0)}^{(\theta)}, \hat{\tau}_{1,k,(0)}^{(\theta')}\}$ when $s_0^k = (0, 0)$.

Pick $\eta < \tau^* - \max\{\hat{\tau}_{1,k,(0)}^{(\theta)}(0, 0), \hat{\tau}_{1,k,(0)}^{(\theta')}(0, 0)\}$ (i.e., a sufficiently negative η) and use (26) so that $\tau^* \geq \max\{\hat{\tau}_{1,k,(0)}^{(\theta)}(\eta, \gamma), \hat{\tau}_{1,k,(0)}^{(\theta')}(\eta, \gamma)\}$. (Again, the same choice yields $\tau^* \geq \max\{\hat{\tau}_{2,k,(0)}^{(\theta)}(\eta, \gamma), \hat{\tau}_{2,k,(0)}^{(\theta')}(\eta, \gamma)\}$, so $(0, 0)$ agents add two on both sides.)

Case 5: $\tau^* \geq \max\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}$ when $s_0^k = (1, 0)$.

Choose $\eta < \tau^* - \max\{\hat{\tau}_{2,k,(1)}^{(\theta)}(0, 0), \hat{\tau}_{2,k,(1)}^{(\theta')}(0, 0)\}$ and use (26).

Case 6: $\tau^* \geq \max\{\hat{\tau}_{2,k,(1)}^{(\theta)}, \hat{\tau}_{2,k,(1)}^{(\theta')}\}$ when $s_0^k = (0, 1)$.

Same argument as Case 5.

In all six cases, by adjusting η , we can move τ^* below all thresholds (so no agent moves) or above all thresholds (so everyone moves equally), thereby making each of the six equality cases feasible. The γ parameter ensures that τ^* continues to sit inside the interior interval from part (a), so the link back to the original proposition is preserved. $\square$
